Hunterian Lectures
ON
SYPHILIS,
AND ON
SOME LOCAL DISEASES AFFECTING PRINCIPALLY THE ORGANS OF GENERATION.

Delivered at the Royal College of Surgeons of England,

By HENRY LEE, F.R.C.S.,
PROFESSOR OF SURGERY AND PATHOLOGY TO THE COLLEGE.

TREATMENT OF SYPHILIS.

Boerhaave, in a treatise on the venereal disease, states that he had not long been engaged in the practice of physic before the continual novelty of cases which occurred to him made him wish that all his reading had been spent among such authors only who, when they had well described a disease, did not omit to point out its most certain remedies. The new symptoms which arise daily in the selfsame disease, and the wonderful disparity among the usual ones, must necessarily leave a physician in the greatest doubt and perplexity, especially when the disease is grown desperate through neglect, or when, by a wrong treatment, it is become the patient's torment and the physician's reproach. All practitioners, he says, agree that no disorder is more liable to these mischiefs than that which we call the French disease. In the management of this malady things sometimes occur which the longest observation is never able to discern; and the oldest artist must, at least sometimes, confess himself a mere novice, and own his ignorance both of the nature of the complaint and its cure. Moreover, it is not uncommon in this disorder to be apprised of things which, though they seem as trifles hardly worth regarding, yet shall soon produce a train of horrible consequences. "Notwithstanding," he adds, "I myself have been a practitioner in this disease for above six-and-thirty years, and although I had always the opportunity of acquainting myself with the nature of this anomalous evil, and made good use of it too, yet has every year produced me something new and unobserved before." Acting upon Boerhaave's suggestion, I shall endeavour to give the treatment, general and local, of the different forms of disease which we shall have to consider; and in the whole range of medicine there are none which yield so readily to treatment as those which form the subjects of these lectures.

The morbid changes observed in constitutional syphilis have been divided into primary, secondary, and tertiary. In uncomplicated forms of the disease, as we have seen, there is no great difference in the kind of action between the primary and secondary symptoms—and the classification of secondary and tertiary syphilis is by no means an easy task. Some have regarded affections of the skin and mucous membranes as secondary, while diseases of internal parts, including the bones, they look upon as tertiary. The secondary symptoms have been supposed to require mercurial treatment, while for the so-called tertiary symptoms iodine, sarsaparilla, and tonics generally have been recommended. Practically, such distinctions are, in my opinion, of little value, and often lead medical men to treat the name which they may happen to apply in a particular case rather than the disease itself. As far as any such classification can be made, that adopted by Mr. Lane is perhaps the best. Among the secondary affections of the skin he classes roseola, lichen, tubercles that may desquamate, ulcerate, or encrust; psoriasis, lepra, and ecthyma. Among the affections of mucous or semi-mucous membranes there are the white aphthous-looking ulcers on the tonsils, soft palate, and fauces, superficial ulcers on the sides of the tongue and angles of the mouth, mucous tubercles or condylomata on semi-mucous surfaces, and deep excavated ulcers of the tonsils. To these are added iritis, muscular pains, arthritic pains, pains in bones, periostitis and nodes. In these affections Mr. Lane considers that the venereal poison still exists, and that it may be communicated by contact and transmitted to the offspring. In such cases Mr. Lane considers mercury as beneficial and iodine of but little or no value.

Tertiary syphilis, affections of the fibrous membranes, include periostitis, resulting in nodes, caries and necrosis of bones; inflammation of fibrous tissues of joints, arthritis; inflammation of the fibrous tissues of the testicles, orchitis; inflammation of the fibrous tissues of the globe of the eye, and sclerotitis.

Among the affections of the skin and mucous membranes in tertiary syphilis are classed rupia and cachectic ulcers of the skin, rapid ulceration of the soft palate, fauces, pharynx and larynx, rapid ulceration of the rectum, vagina, nymphæ, and labia.

In the same class are included deposits of fibro-plastic lymph, imperfectly organised—first, in the areolar tissue, constituting subcutaneous or submucous tubercles; and, secondly, in the muscular tissue. These are frequently met with in the tongue, and occasionally in other muscles; and similar deposits are met with as post-mortem appearances in the liver, spleen, kidneys, lungs, and other viscera. To this list Mr. Lane adds lardaceous and waxy deposits, occasionally found in the post-mortem examination of the bodies of persons of dissipated habits.

The pathological changes in this class occasionally, according to Mr. Lane's view, present themselves in patients who have passed through the primary and secondary stages of syphilis, but in whom the venereal poison no longer exists, and therefore cannot be transmitted. The remedies required in these affections are especially iodine and sarsaparilla,—and mercury, in Mr. Lane's opinion, is injurious.

Some such classification as the above is necessary for systematic teaching, and that now given I believe to be perhaps the most convenient that has yet appeared. But I am satisfied that no such classification can be practically relied upon, either as a matter of pathology or with regard to treatment. A node, for instance, which is generally supposed to be among the latest manifestations, will sometimes be the first symptom to attract attention; and, on the other hand, I have seen a well-developed syphilitic scaly eruption on the arm of an Indian officer who had had no primary affection for seven-and-twenty years.

The morbid processes which Hunter has described, without reference to time in this as in other diseases, are those which are the most true to nature, and which furnish the most reliable indications for practice.

At whatever period of the disease we find the existence of the specific adhesive form of action, whether developing itself as a primary manifestation in the shape of an indurated sore, or as an affection of the inguinal glands, or in the form of papular, tubercular, or scaly eruptions on the body, mercury is, in my opinion, sure, if properly administered, to be beneficial.

When the disease, whether primary, secondary, or tertiary, has a tendency to produce suppuration in the affected parts, mercury should be administered with great caution.

The same may be said, as a rule, where the affected parts run rapidly into ulceration, although in some of these, to be subsequently considered, one form of mercurial treatment is wonderfully efficacious.

Where mortification takes place, whether affecting minute or larger portions of the tissues of the body, mercury given so as to affect the constitution is, as a rule, injurious.

Mr. Pearson states that his opportunities of administering mercury had not extended to less than twenty thousand cases, and that he felt himself fully authorised to assert that it is a remedy always to be confided in, under every form of lues venerea; and that, where we have only that one disease to contend with, it is a certain antidote, and as safe in its operation as any other active medicine drawn from the vegetable or mineral kingdom. "Let me not be misunderstood," he continues, "to say that it is a certain and safe remedy in the hands of anyone who undertakes to dispense it. Quite the contrary; for a multitude of indisputable proofs might be adduced that ignorance and error often render it one of the most precarious and mischievous medicines in use." Mr. Pearson goes on to say:—

"The superior efficacy of mercury, as the genuine antidote of syphilis, is sanctioned by the experience of three hundred years; and, what is a circumstance deserving of consideration, not one medicine besides, derived from the animal, vegetable, or mineral kingdom, has maintained its credit, with men actually employed in extensive practice,

No. 2711.

during a tenth part of that period. Perhaps it would not be rash to assert that no other medicine has maintained a general good reputation as a specific against the venereal disease beyond the lifetime of its first proposer.

"Men may amuse themselves by declaiming against mercury as an uncertain remedy; they may utter querulous details of its baneful effects, and retail tragical stories of its malignant influence on the body and mind of those who use it; but surely all this turbulent eloquence may be directed with equal advantage, not only against every potent article of the materia medica, but against the very aliment by which we are sustained.

"Almost every department of physical science contains propositions which require exceptions, or against which objections may be brought that scarcely admit of a satisfactory solution. Yet, notwithstanding these, philosophers do not suppose it necessary to abandon duly verified axioms, because a few phenomena, not perfectly understood, seem to militate against them.

"He who shall discard all general rules, because they admit exceptions, ought likewise, for the sake of consistency, to renounce all science, because human knowledge is fallible and imperfect."

In recommending the use of mercury as an anti-venereal remedy, before all others yet introduced into practice, Mr. Pearson says that he neither intends "to conceal or deny that real inconveniences are sometimes connected with the administration of that medicine. There are certain peculiarities of constitution, where its irritating qualities predominate over its medical ones, and where the mode of its agency seems rather calculated to distress the patient, and to injure the health, than to remove the disease for which it is exhibited; hence it were highly desirable to acquire a medicine equally potent as an anti-venereal, and not possessing certain active properties peculiar to that mineral. But this concession forms no valid objection against mercury exclusively.

"There are other articles of the materia medica which produce ill effects on the animal system, even when administered with the utmost skill and judgment. It is sufficiently known that antimony, ipecacuanha, Peruvian bark, opium, digitalis, rhubarb, magnesia, honey, &c., when brought into conflict with certain idiosyncrasies, will excite great and serious mischief; the primary and direct effect of these medicines, on one or more parts of the animal system, militating absolutely against their medicinal qualities. But exceptions of this kind make no impression upon the minds of considerate men, unfavourable to the generally acknowledged merits of these drugs; they note the particular instances, and substitute other medicines in their stead, which possess qualities corresponding to the indication.

"The wish which I have expressed, that another medicine could be found on which reliance could be placed for the cure of lues venerea, does in no wise spring from any distrust of the sufficiency of mercury; it originates merely from the same source which would induce me to desire that the means of remedying every form of human misery were abundantly multiplied."

Mr. Pearson adds:—"I regard every effort used to increase the store of useful medicines as highly meritorious; and, notwithstanding my firm persuasion of the safety, efficacy, and pre-eminency of mercury, in all cases truly venereal, yet I should be guilty of a very perverse and contracted mode of thinking were I to oppose the introduction of another specific, or censure the experiments made to ascertain its intrinsic merits. What number of specific medicines may yet lie concealed among the arcana of nature can form no proper subject of conjecture; but that mercury is as indubitable a specific against lues venerea as any one article of the materia medica is against any one malady, is a fact too authentic to be disputed by any who have either employment or reputation to lose; and as for those who possess neither, their suffrages are not worth collecting."

Although we have, since Mr. Pearson wrote these remarks, now seventy-four years ago, had many new remedies introduced, and some of them of great efficacy in their way, yet I would still endorse his opinion that there is no remedy like mercury for the cure of syphilis. The iodide and bromide of potassium stand pre-eminent among the medicines introduced since Mr. Pearson's time, but their value consists, in my opinion, in removing symptoms, not in curing the disease. I am of course aware that after a person has once had syphilis an impression is left upon his system which is not effaced for years, and perhaps not at all, and what I therefore mean by a patient's being cured, is, that he shall have no further manifestations of the disease. That this condition is often obtained by a proper course of mercury I cannot doubt. I have now seen a large number of patients who have told me that since they underwent a mercurial course they had remained well, and many of these had not had any return of the symptoms for between ten and twenty years. Out of Mr. Pearson's 20,000 cases, a considerable number probably were instances such as I shall have hereafter to describe of local disease, which, with time, would doubtless have got well under the use of guaiacum, sarsaparilla, mezereum, walnuts, opium, the Peruvian bark, the mineral acids, the muriate of barytes, or any other of the remedies at the time in use, or even under no treatment at all. But no one can doubt but that a large proportion of Mr. Pearson's cases were really syphilitic, and were cured by mercury in a way that they would not have been by any of the other remedies which, in other cases, he had tried so extensively. Mr. Pearson's wish that another medicine, equally potent as an anti-venereal, and not possessing certain active properties peculiar to mercury, might be found, has then been realised—but much has been done in the same direction, not by finding a new remedy, but by administering an old one in a different way.

Mr. Pearson mentions that he had so far modified the treatment of syphilis by mercury that he did not consider it necessary to produce ulceration of the gums, and he was satisfied if the action produced a spitting of from half a pint to a pint a day. Coming more near to our own times, the general treatment was, perhaps, that described by the late Mr. Cutler, in the Report of the Committee appointed in 1864 to inquire into the treatment and prevention of venereal diseases in the army and navy. He says:—"As soon as I find that the breath is affected, or the gums are affected, or that the skin is very much affected, or that diarrhœa is produced, I consider that the patients are quite under the influence of mercury."

Mr. Cutler is asked whether he had ever witnessed the treatment of constitutional disease without mercury?—and he says that when he came to London the late Mr. Rose was surgeon to St. George's Hospital, and was then also surgeon-major in the Guards, and he wrote his paper on the anti-mercurial treatment. He then stated that he had never given one grain of mercury to any patient in the Coldstream Regiment of Guards for two years. Mr. Cutler got a letter of introduction to Mr. Rose, in order to see his practice at the St. George's and St. James's Infirmary, and to his surprise he found that nine out of ten of the syphilitic patients were taking mercury. Mr. Cutler asked, "Have you returned to the mercurial treatment?" "To be sure I have," said Mr. Rose. "I only wanted to prove that the disease in the bones and the worst form of secondary symptoms were occasioned by repeated courses of mercury," which were then given in all cases, whether the patients were debilitated by consumption or any other cause. Mr. Rose further stated that even in the Guards he found one case out of every three followed by secondary symptoms with the non-mercurial plan of treatment, and that this did not occur once in ten times when mercury was administered. The mercurial treatment, Mr. Rose also considered, cured patients in half the time required by the non-mercurial. I may add that, even with regard to those who were supposed to be cured without mercury, the evidence is not quite satisfactory, for I was informed directly by one who was in the secret, and who himself afterwards did some business in the same line, that a large number of the soldiers in the Guards, who were supposed to be undergoing the non-mercurial plan of treatment, were in the habit of resorting to a person living in Knightsbridge, who sold them quantities of medicine containing bichloride of mercury. But this was only a repetition of what had long before occurred. Mr. Pearson mentions that in the time of Morgagni mercury was interdicted by some of the most eminent physicians of Italy, and that strong prejudices existed against it as late as the middle of the eighteenth century.

Mr. Cutler's assertion, and the teaching of those who held the same opinion, that when the patient's breath became affected the patient was sufficiently under the influence of mercury, has led to a very wide-spread and mischievous error. It was assumed, and is still thought, by a large number of practitioners, that the mercury should be then discontinued. Nothing is more common in the history of a case than the statement that the patient's gums were touched and the mercury discontinued. Such, certainly, was not Mr. Cutler's practice. What he meant was that the mercurial action should not exceed that which he mentions, and his practice was to continue that action for a considerable period. It is true that when the internal administration of mercury affects the bowels to any great degree, or produces much salivation, that mode of administering mercury has to be given up; but all who have had much experience in the treatment of syphilis know that the disease is not cured in this way. The observations of Sir Benjamin Brodie are here quite in point. He says that, "except in the slighter forms of the disease, we really cannot depend upon the internal administration of mercury for a cure. We may in this way patch up the disease, but it will return over and over again." One reason of this is obvious—namely, that the mercury, in a very great majority of cases, irritates the bowels, so that it has to be left off before the patient is cured, and on a recurrence of the symptoms the patient perhaps is, on the whole, in a worse condition, as far as his constitution is concerned, and certainly in a less favourable state for proper treatment, than he was before. Sir B. Brodie, following Mr. Pearson, gives the decided preference to the inunction of the mercurial ointment to all other plans of treatment in use in his time. He says:—

"When the symptoms are not of a mild character, the patient should, if possible, be confined to the house, except perhaps for an hour or two in a fine day. The going out into the fresh air (as Mr. Pearson observed long ago) will counteract the influence of mercury. You never can be responsible for thoroughly eradicating the disease where the patient is at all exposed to cold or wet, nor where he does not lead a most regular and careful life in all respects.

"In all cases of syphilis in which you employ mercury, remember that you have two objects in view: the first, to cure the present symptoms; the second, to prevent a return of the disease. It seems to me that a great number of practitioners at the present day regard only the first object, and lose sight of the second. I have frequently seen a person who has taken mercury for a chancre, which has, perhaps, healed in a fortnight, and then has left it off, although a very hard cicatrix has been left. Under such circumstances, in nineteen cases out of twenty, there will be secondary symptoms. If mercury be taken for the primary symptoms, the patient should never leave it off till the hard cicatrix has disappeared, nor indeed for some time afterwards: and so, where it is given for secondary symptoms, it should be continued for a considerable time after they have disappeared. A man has an eruption of the body; it fades away, under the use of mercury, in the course of a month; but the remedy must be used as a prophylactic for another month. If a patient be confined to his house, or only allowed to go out a little in a fine day; if he be made properly to rub in the ointment, and the course be carefully watched and continued for some time after the symptoms have subsided, you will, I am satisfied, in the great majority of cases, make a real and permanent cure of the disease. I suspect that this is not the way in which it is administered by the majority of practitioners at the present time, but it was so administered formerly. You must not suppose that we have advanced alike in all departments of surgery; indeed, I am sure that in some things we have gone back, and I believe this to be one of them. I am much mistaken if the mercurial treatment of syphilis, as employed by the late Mr. Pearson during the greater part of his life, was not as nearly perfect as possible. At any rate, it was much more successful than the less careful treatment of modern practitioners. That gentleman was surgeon to the Lock Hospital; and having no general hospital to attend to, the powers of his mind were more especially devoted to the study of syphilitic diseases and their treatment; and the practice which I have now recommended was that which he usually adopted. When I was young in my profession I had frequent opportunities of meeting him in private practice, and of learning how profound a knowledge of the subject he possessed; and I may take this opportunity of recommending for your perusal his treatise on the various articles of the materia medica recommended for the cure of syphilis, in which he offers many excellent observations on the use of mercury, and enters into details in a way in which it is not my object to enter into them at present."

The preparations of mercury generally used were the blue pill, the mercurial ointment, calomel, corrosive sublimate, and the iodides and bromides of mercury; for fumigation, the grey oxide and the bisulphuret.

On account of its convenience, and the little trouble it gives, the administration of mercury in the form of pills is that which the patient prefers. But mercury can seldom, if ever, be given in this way long enough to cure the disease. It acts upon the patient's stomach and intestines before it has accomplished its object, and it then has to be discontinued. It may for a time, however, be usefully employed either by itself or in combination with external treatment. Three grains of blue pill, with half a grain of opium, night and morning, or half a grain or a grain of the iodide of mercury, with a quarter of a grain of opium, night and morning, are convenient modes of giving mercury internally, and will in general soon produce its specific action. The corrosive sublimate or perchloride of mercury can never be trusted to for the cure of syphilis, although it is a valuable auxiliary in some stages of the disease.

The inunction of the mercurial ointment is the plan of treatment recommended by Mr. Pearson and Sir B. Brodie. This answers very well if a patient will carry it out, but it is not often in private practice that this can be accomplished. It involves a considerable amount of trouble, and the patients object to the dirty appearance on their skin and on their clothes. This last objection has of late been partially removed by the introduction of the oleate of mercury. In some patients the skin does not bear the inunction of mercury well. A crop of pustules not unfrequently appears, and this sometimes gives the patient a considerable amount of annoyance. Mr. Pearson was in the habit of commencing by the inunction of half a drachm of strong mercurial ointment every night, and he was very particular during the treatment not to allow the patients to be exposed to the influence of cold air. He kept them to their room, and sometimes to their bed. The advantage of this plan he found to be that the stomach and bowels did not often suffer from the action of mercury as a metallic salt; a larger quantity of mercury could be administered; the specific powers of mercury could be obtained with great certainty, and sometimes advantage might be derived from the friction being employed near the seat of the disease. The inconvenience of the pustular eruption he found might be avoided by previously shaving off the hairs. All acids during a mercurial course were forbidden, and even tea, if it became acid on the stomach. No vegetables except potatoes were to be eaten, and occasional aperients were administered, as it was found that a common effect of the plan of treatment was to induce constipation. Mr. Pearson was in the habit of increasing the quantity of mercury used to one or two drachms, or even half an ounce. The salutary or specific and injurious effects he thus sums up:—

1. It may prove fatal by acting as a metallic salt, in which case it produces vomiting, fainting, diarrhœa, and dysentery. Where such symptoms arise, even if unattended with danger to life, the treatment will fail in its specific operation.

2. It may act as a mineral poison, not by its direct action upon the stomach, but by producing erethismus, inflammation of the joints, effusion into the bursæ, ill-conditioned ulcers, mortification of parts, and great debility. In all these cases the mercury acts as a mineral poison, affecting very much the mind and the constitution in general, and not producing its beneficial effects on syphilis.

3. Mercury often acts beneficially by promoting perspiration.

4. It promotes the urinous secretion, frequently rendering it turbid and offensive, and liable to deposit a white sediment.

5. It often produces inflammation of the glandular surface of the mouth, swelling of the tongue, and sponginess of the gums.

6. It promotes increased secretion of saliva, producing ptyalism.

7. It sometimes induces powerful depression of the animal functions.

The increased secretion from the skin, kidneys, and salivary glands, with depression of the animal spirits, were considered consistent with its operation as an antidote.

Mr. Pearson was of opinion that the gums should always be made tender and spongy, but this was only to be considered as an evidence of the action of the remedy, and as constituting no essential part of the process of cure. The plan of treatment was continued, if possible, until the symptoms had disappeared, and for some time afterwards, and this might occupy from seven to nine weeks.

I have been particular in giving an account of the action of mercury in Mr. Pearson's day, as, under the milder treatment now pursued, some of these results are seldom seen and little known. But another evil has crept in—namely, that patients who have been supposed to have undergone a mercurial course have done so very inefficiently; the gums have perhaps been "touched," the mercury has then been discontinued, and the disease has remained.

ABSTRACT
OF THE
ADDRESS IN PHYSIOLOGY,

Delivered before the Annual Meeting of the British Medical Association, at Edinburgh, August, 1875.

BY WM. RUTHERFORD, M.D., F.R.S.E.,
PROFESSOR OF THE INSTITUTES OF MEDICINE IN THE UNIVERSITY OF EDINBURGH.

THE VIVISECTION QUESTION.

PROFESSOR RUTHERFORD in his opening remarks said that much had been done in Germany and elsewhere to detach physiology from medicine, and develop it as a branch of purely natural science. Such a development, however, gave to physiology an aspect somewhat different from that which it wore when it was regarded, as in the Scotch schools, as the Institutes of Medicine. Therefore the latter title was useful to the teacher, inasmuch as it reminded him that he was more especially to dilate on those facts of physiology which were of value to the medical practitioner. Physiology was an experimental science. Apart from those which were the results of artifice, experiments of great physiological significance were being continually wrought by accident, and by disease, and the science had owed much in the past to those engaged in the daily study of those pathological experiments. Assuredly they could not afford to detach physiology from medicine, for, without doubt, in the future as in the past, the study of those bodily conditions that were abnormal would throw much light on those that were normal; while, on the other hand, those whose knowledge of physiology was most profound were precisely those who, as physicians, were able to conduct pathological analysis with skill and success.

At present there was reason for some anxiety in regard to the manner in which this much-needed knowledge of the Institutes of Medicine was to be attained by their students. In recent years the teaching of physiology had made a great stride in this country. Laboratories duly appointed had been and were being organised; and the method of physiological instruction had in most instances passed from the mere prelection illustrated by diagrams to an experimental exposition of the subject. In his student days the latter element was wanting, and at this moment there was distinct danger of a return to something like that miserable mode of instruction in consequence of the fanatical clamour of a number of persons excited, it must be admitted, by one or two members of their own profession. He could not suppose that any member of the Association entertained the idea that experiments on the lower animals were not justifiable for the discovery of new truth; but he was aware that there were some who entertained the idea that vivisection was not necessary when it had for its object the mere demonstration for educational purposes of facts already known. Those who held this doctrine appeared to him to forget that physiology was an experimental science, and that no right conception of the subject could be obtained unless the student was shown the experiments that were necessary for the demonstration of certain facts. No language, however clear, could depict the movements of the heart, of the circulation of the blood, so as to call forth a picture so vivid and true as that which without an effort sprang forth the moment those things produced an impression through the organ of sight. The manner in which the blood pressure was affected by retarding the heart's action, by dilating the arterioles, or by muscular contraction, the changes which followed division of the sympathetic nerve in the neck, the result of stimulating the cortex of the brain, the reflex power of the spinal cord, the tetanus from strychnine, and the paralysis of voluntary movement produced by curara—these and other equally great fundamental facts in physiology gave rise to nothing more than vague and feeble conceptions unless they were witnessed. Had not every teacher repeatedly observed the altogether different mental attitude which students assumed the moment he passed from mere description to a demonstration of phenomena? He far more forcibly arrested their attention, and far more deeply imprinted on their minds the facts he would bring home to them. The student was apt to forget that which he had merely been told, but the impression of that which he had seen was with difficulty effaced. There was, however, a great deal more than this. It was not enough that the student of medicine should be crammed with so many facts about the bodily machine; it was of infinitely greater importance that he should be really educated in a knowledge thereof. He could not be educated unless it was assumed that he had a right to question statements made to him, and to demand a demonstration of the truth of what was said. It was not enough that the teacher merely said in an *ex cathedrâ* manner that this or that was so; he ought on all possible occasions to prove to the students that it was so; he ought to appeal to them as individuals who could and ought to think for themselves, and therefore as individuals who were not merely to be crammed, but to be convinced. Every examiner in physiology must have repeatedly observed how glibly a student might repeat a statement of fact, but how sorely puzzled he often appeared when asked for the evidence on which his statements were founded. Moreover, everyone must have noticed how often the student lacked knowledge that was definite, and mingled together things that were uncertain with things that were certain, because he had not been sufficiently trained to examine experimental evidence. Of how little avail was this unreasoning knowledge when the student came to thread his way through the difficult analysis of disease! He either believed, or he doubted, too much; he oscillated from one extreme to another, because he was wanting in definite knowledge, and because his critical power had not been sufficiently developed. Now, he maintained that this definite and critical knowledge regarding the bodily organism could not be attained unless their students were shown experiments on living animals, and he held that those authorities who seemed to be of opinion that this method of tuition might be dispensed with, were entirely overlooking the vast importance, not only to the student himself, but to the whole race, of an experimental manner of laying the foundation of a knowledge of the institutes of medicine. It was, he believed, too much to assume that those who advocated a flimsy and superficial method of teaching physiology were altogether actuated by feelings that were termed humane. He feared there was lurking behind that disposition a feeling of indifference to what were the true principles of medical education; or, what was more likely, there was an incorrect appreciation of those principles. It must, however, be admitted that, notwithstanding the vast importance of physiological experimentation in the teaching of medicine, the circumstances under which it was displayed demanded serious consideration. No one could deny that animals daily suffered pain in order that they might be eaten by man, and also that man might not be eaten by them. If it was thought necessary to put countless animals to a painful death for the purpose of keeping the human race alive, might not physiologists inflict pain, not only for the discovery of new truth, but also for the right education of those who had to spend their lives in preventing or in healing disease? Was the one object of less importance than the other; indeed, was not the object in both cases precisely the same? Why, then, this clamour against physiologists? The pain produced in all the physiological experiments performed in this country in the course of a year was, he believed, as nothing compared to that inflicted upon animals by Her Majesty's Lords and Commons on an autumn holiday. He would not, however, for a single moment speak lightly of the production of pain, for it was the function of those who pursued medicine to alleviate pain and suffering. Their students would indeed be badly trained for the pursuit of a calling so humane as that of medicine, if they did not find their teachers on all occasions carefully avoiding the giving of pain that was not absolutely necessary. Therefore it was their duty, for this as well as for other and obvious reasons, to use narcotics in their experiments upon animals whenever it was possible. It was not necessary for a sound physiological education that their students should be shown all the experiments that were needed to demonstrate physiological truths; they probably did enough if they showed experiments on the cardinal points of physiology; and he averred that all the experiments on the higher animals that were really required for the purpose of education could be performed with the aid of narcotics. Seeing that this was so, why should it be that some had become convinced that, in consequence of the present inflamed state of the popular mind on the subject of vivisection, the right education of medical students must be abandoned? The popular mind had been abused by inaccurate and misleading statements regarding both their motives and their actions. He maintained that a great and deplorable error was committed when the unreasonable clamour of the anti-vivisectionists was met in the spirit of compromise instead of the spirit of stern resistance. He believed that the unfortunate Vivisection Bill which was laid on the table of Parliament conferred a dignity on the policy of the anti-vivisectionists which but for that Bill it would probably never have possessed. It was true that there had been a withdrawal of that singular Bill, according to which they were to have been fined fifty pounds or to have been sent to prison for two months if they had dared to show to their students any experiments, even upon a narcotised animal. But the effect of the Bill was not effaced; the increased boldness which it had given to the pretensions of the anti-vivisectionists was only too evident. All that they could now hope was that the good sense of the Legislature would in the end prevail, and that it would do nothing to hamper the education of medical men.

The learned Professor went on to explain, with the help of numerous diagrams, the results of a series of experiments he had made in reference to the action of certain drugs on the biliary secretion of the dog. These results, briefly stated, were as follows:—Croton oil was not found to be an important hepatic stimulant; podophyllin stimulated the liver enormously, and caused the production of a bile almost the same as that which was secreted without its action; aloes was a very distinct hepatic stimulant, and produced less intestinal irritation than podophyllin; rhubarb never failed to increase the secretion of bile, almost the same in character as that secreted without its help, while it caused less intestinal irritation than either podophyllin or aloes; senna stimulated the liver, but not to the same extent as rhubarb, and it seemed to render the bile more watery; colchicum caused the secretion of a large amount of biliary matter; taraxacum stimulated the liver, but not to any very great extent; scammony excited the liver, but not to a marked extent; calomel increased the secretion of bile in one experiment, but three others appeared to show that it was not a hepatic stimulant, at all events in the dog; gamboge produced strong intestinal irritation and profuse purgation, with a fall in the secretion of bile, probably owing thereto; castor oil showed decided purgative action, but produced a slight stimulation of the liver; alcohol did not increase the secretion of bile. It thus appeared that podophyllin, rhubarb, aloes, and colchicum had the most marked effect in increasing the biliary secretion of the dog; and as to their mode of operation, it appeared most probable that they were absorbed and directly affected the liver, though on this point it was not professed that anything had been definitely settled. A far more important practical point was the following:—How was it that these experiments proved podophyllin to be a hepatic stimulant, while in the experiments of the committee presided over by Dr. Bennett it was found that that substance diminished the amount of bile secreted? The only apparent explanation was that in the present experiments the dogs had been kept fasting for seventeen or eighteen hours, while in those of the committee they had had their usual food. The clinical observer would probably accept the facts as not opposed to clinical experience as regarded man, except in respect of calomel. It had simply been shown that while there were a number of substances supposed to be cholagogues in man which excited the liver of the dog, calomel was not one of these, although in the dog, as in man, it produced purgation, and although the researches of Dr. Bennett's committee conclusively showed that dogs could be salivated by mercury as well as man.

ABSTRACT

OF THE

ADDRESS IN SURGERY,

Delivered before the Annual Meeting of the British Medical Association, at Edinburgh, August, 1875.

BY JAMES SPENCE, F.R.S.E.,
PROFESSOR OF SURGERY, EDINBURGH UNIVERSITY.

PROFESSOR SPENCE, in the outset of his remarks, said that looking at some of the more prominent changes in surgical practice, a superficial observer might almost imagine that, instead of progressing, the science moved in a cycle, and were he disposed to be cynical, he might suggest that practitioners had come back to sheer mechanical force, complicated dressings, and red-hot knives. On more careful examination, however, it would be seen that even in cases where the practice was not absolutely new, the method of applying it had been so modified and improved as to constitute a real advance and acquisition to the surgeon's resources. In illustration of this proposition, Mr. Spence went on to speak of the method of treating fractures by extension, the development of periosteal surgery, the reduction of dislocations, the bloodless method of operating, and the treatment of croup and diphtheria, between which latter diseases he drew a broad distinction. The statements made had reference to a large extent to cases which had come under the lecturer's own observation, and were elucidated by diagrams and preparations.

Proceeding to speak of the treatment of wounds and surgical dressings, the learned Professor contrasted the old practice, in which stress was laid on digestion, mundification, and incarnation, and no wound was allowed to heal by first intention, with the truly philosophical views of the adhesive process taught by Hunter, and nowhere more intelligently carried out than in Edinburgh, through the influence and the writings of John Bell, Liston, and Syme. The results obtained from the latter system were, he said, excellent, and the system remained in use to the present time. Now, however, they were again in a transition state in regard to the treatment of wounds. The antiseptic method of Professor Lister was being pressed, in some quarters, to the exclusion of conditions which he could not but think, at least equally, if not more important in the treatment of wounds and operations. The present was not the place, nor was there time, to discuss the germ theory of putrescence, or the general value of the antiseptics now contending for pre-eminence; but some of the statements advanced for the antiseptic system so ignored the effects obtained by the simple dressing and treatment of wounds, and such infallibility was claimed for the effect of the special method, as to require some notice. When he read statements that the antiseptic method was to be regarded as one of the most important contributions to modern practice, inasmuch as it made wounds heal by first intention, instead of going through the painful processes of granulation and suppuration, he could only regard such statements as arising from want of experience in, or misrepresentation of, the simple method of treating wounds; for assuredly healing by granulation was neither the object nor the general result of that plan of treatment. Suppuration, he believed, was not unknown in the antiseptic system, whilst the average duration of treatment, as far as he could learn by hospital statistics, was not lessened. But when he found a German professor and hospital surgeon stating that, after a year and a half's experience of the antiseptic treatment he was able to guarantee with certainty the perfectly successful result of his operation, such an assertion challenged closer examination, and one demanded proof on the question how far, apart from other conditions, different modes of dressing stood in the relation of cause to successful results. The answer to this important question must rest on sufficient data—carefully weighed statistics. It would not do to point to some brilliant results in individual cases, because all methods of treatment could produce that kind of proof. Nor would it do to state that no death from pyæmia had occurred under the system. The statistics must indicate the nature of the disease or injury for which the operation had been performed, and the cause of death in fatal cases, not by a conventional term, but by giving the symptoms during life, and the organic lesions found after death. With extensive statistics of this kind, they should be better able to judge of the comparative advantages of different systems. It was curious that they heard so much of success from abroad; and he thought that sufficient time and scope had been given to the system in this country to enable those who used it to furnish statistics such as he had indicated, and thus enable the profession to judge more dispassionately of its results.

In comparing of late the results of his own hospital practice, he had been struck with the success which attended a very simple treatment; and this led him to question their progress in departing from it. During three years, out of sixty-three major amputations for disease, there were only three deaths; and out of twenty-three cases of excision of joints, only two deaths. The treatment consisted in thoroughly washing the surface of the wound by pouring tepid water over it, occasionally applying tincture of iodine on the flap, while the dressing consisted in a fold of lint or thin muslin over the same. Again, in preparing statistics of his amputations, he found evidence that certain conditions, such as the nature of the disease or injury, had a most important influence on the result; such an influence, indeed, as he could hardly have supposed till the statistics brought it distinctly before him. His later statistics corroborated his former; so that he could not accept the statement of the learned German professor to which he had referred.

Whilst he spoke of the antiseptic system, meaning the special method, he need hardly say that all surgeons had for their object the avoidance of putrescence, though their views might differ as to the best way of attaining it. He could not close without recommending the advantage, in treating lacerated wounds and burns of the extremities, of continuous immersion in the tepid bath and avoidance of all meddling with the injured part and the agony to the patient caused by the changing of dressings. In the case of burns especially its advantages were most conspicuous, for the constant moisture kept the superficial tissue pliable, and motion of the parts could be effected gradually while the limb was immersed in the bath. Here the antiseptic method could be carried out most thoroughly by mixing carbolic acid with the fluid in which the limb was immersed. The retrospect he had taken showed that when true principles had been disregarded or lost sight of they had ultimately had their value recognised, and, modified and improved, had become the advances of the present. So, for the future, he felt confident that all that was true and good in any system might emerge with all the greater beauty and usefulness that it had been purged of its dross by the test of observation and candid inquiry.

Dr. Frankland reports that the condition of the London waters during July was satisfactory. The advantage of the storage of river water in reservoirs is shown in the state of the West Middlesex water, which, in consequence of longer storage, exhibited scarcely half as much evidence of previous sewage or animal contamination as the Lambeth Company's water, though both are derived from the same source.

ON THE

DIAGNOSIS OF ENLARGED BRONCHIAL GLANDS IN CHILDREN.

By EUSTACE SMITH, M.D., F.R.C.P.,
PHYSICIAN TO H.M. THE KING OF THE BELGIANS;
PHYSICIAN TO THE EAST LONDON CHILDREN'S HOSPITAL;
ASSISTANT-PHYSICIAN TO THE VICTORIA-PARK HOSPITAL FOR DISEASES OF THE CHEST.

Enlargement of the bronchial glands is a very common lesion in early life. In many children the lymphatic glands generally over the body enlarge upon the slightest irritation, and when once swollen are slow to return to their natural size. It is in these cases that cheesy degenerations are apt to occur in the swollen glands, and suppuration, with the formation of an abscess, may be the consequence. This is common in the case of the cervical glands, and happens sometimes in those of the chest. In any case the presence of a cheesy mass is not unattended with risk, and its very existence is a sign of that vulnerability of constitution which predisposes to the so-called consumptive diseases, and is a constant source of danger.

Children who have been subject to repeated attacks of pulmonary catarrh are very liable to enlargement and caseation of the bronchial glands. Whooping-cough is also apt to leave behind it the same condition, and after measles it is frequently met with.

The seat of the enlarged glands is at the bifurcation of the trachea, and therefore behind the first bone of the sternum, and a little below it. They give rise to dulness on percussion at this spot, and the dulness often extends to each side of the bone, and also downwards to the upper part of the second bone. In the case of young children there is sometimes in health a little dulness on percussing the upper bone of the sternum, produced by the underlying thymus gland, but the dulness does not in such cases reach laterally beyond the limits of the manubrium. In the case of great enlargement of the bronchial glands there may be dulness also behind in the intrascapular region, but this is rare on account of the thickness of lung which intervenes between the glands and the posterior wall of the thorax.

The symptoms by which enlargement of the bronchial glands can be distinguished—viz., distension of the cervical veins, swelling of the neck, dyspnœa, spasmodic cough, and whispering voice—are all pressure signs due to the encroachment of the swollen body upon the parts around. They are, therefore, not present until the increase in size of the glands has become considerable. In these cases the dulness on percussion is usually marked, and if the glands are of sufficient size to compress the trunks of the large vessels, the ordinary stethoscopic signs of such pressure will be heard. At this stage the nature of the case is obvious; but at an earlier period, and before the enlargement has become sufficiently great to give rise to the signs enumerated above, the diagnosis of the lesion is much less easy, as the symptoms by which it is accompanied are few and obscure. At this time much assistance can be gained from the following experiment. If the child be made to bend back the head so that his face becomes almost horizontal and the eyes look straight upwards at the ceiling above him, a venous hum, varying in intensity according to the size of the diseased glands, is heard with the stethoscope placed upon the upper bone of the sternum. As the chin is now slowly depressed, the hum becomes less loudly audible, and ceases some time before the head is brought back again into the ordinary position. The explanation of this phenomenon I believe to be that the bending backwards of the head throws forward the lower end of the trachea, which carries with it the glands lying in its bifurcation, and the left innominate vein, as it passes transversely behind the first bone of the sternum, is compressed between the enlarged glands and the bone. In cases where this sign has been present there has often been some slight dulness over the manubrium, leading one to suspect the existence of enlargement of the glands, and the occurrence of the hum thus produced I now always consider to be evidence confirmatory of the suspicion. The experiment does not succeed in cases of flat chest where there is no reason to suspect glandular enlargement, nor can the hum be produced by the thymus gland in a healthy child. This gland lies immediately behind the sternum in front of the great vessels; enlarged bronchial glands lie behind the vessels in the bifurcation of the trachea. A swelling in front of the vessels does not appear to set up pressure upon the vein when the head is bent back in the position described. I have examined many children, with a view to test this point, and in no case have I found the characteristic hum produced except in cases where there was reason from other symptoms to suspect the presence of bronchial glandular enlargement.

The following cases furnish good illustrations of the symptoms in question:—

Arthur P——, aged eight years, had had scrofulous disease of the knee-joint for twelve months. The cervical glands were enlarged, and his skin generally was harsh and dry. For two months his breathing had been short, although he had had no spasmodic attacks of dyspnœa. During the same time he had been troubled with a dry hollow cough. There was slight dulness at the left supra-spinous fossa, and a little crepitating rhonchus was heard there at the end of inspiration. There was no dulness on percussion at the upper part of the breast-bone, but when the boy held his head back so as to turn the face upwards to the ceiling a loud continuous hum was heard near the left edge of the front bone of the sternum, and this ceased when the chin was brought down again into the natural position. This boy had no swelling of the cervical veins, spasmodic cough, or other sign of enlarged bronchial glands, except the peculiar and characteristic hollow, almost cavernous, breathing which is often heard in such cases, when the lips are closed, over the upper part of each lung. This, however, disappeared to a great extent when the mouth was open.

Alice T——, aged six years, a pale, thin child, had been weakly for several months, and had been getting thinner. She had no cough to speak of. On stripping the child to examine her chest, it was noticed that the superficial veins at the upper part of the breast-bone and at either side were unusually visible. The veins of the neck were not distended, nor was there any enlargement of the cervical glands. The percussion note on the front bone of the sternum was perhaps a little high-pitched, and when the child bent her head well backwards, a very loud continuous roaring sound was heard over the first two sternal bones, and extended to the articulation of the second right cartilage. The sound ceased when the chin was depressed again. There was no dulness in the intrascapular region behind.

It would be easy to multiply illustrations of this symptom, for disease of the bronchial glands is very common in children. I believe the hum in the vein to be capable of being produced in every case where the glands of the chest are enlarged, so long as these are movable. If they are fixed, and at some distance from the sternum, the experiment fails. Thus, in a boy aged three years, the subject of lymphadenoma, who died in the East London Children's Hospital under the care of Dr. Bruce, there was dulness at the upper part of the breast-bone, which was continued down in a pyramidal form as far as the heart's dulness. No venous hum, however, was produced by bending back the head. On examination of the body of this child, yellow flattened cheesy masses were found adherent to the inside of the sternum, and others much enlarged and immovable were seen filling up the interval between the bifurcations of the trachea. In this case the alteration in the position of the head did not set up pressure upon the vein, as the glands being fixed could not be carried forwards against the vessel.

The venous hum thus produced by bending back the head I believe to be the earliest sign of enlargement of the bronchial glands in a child, preceding dulness on percussion, an occurring long before the ordinary pressure signs on which the diagnosis of the lesion is usually made to depend.

George-street, Hanover-square, W.

THE TREATMENT OF DISEASES OF THE HIP-JOINT.

By H. C. ATTENBURROW, F.R.C.S.,
LATE SURGEON TO THE NOTTINGHAM HOSPITAL.

On January 5th, 1874, I was called to see a child named H——, aged eleven years. The left leg was two inches shorter than the right; there was no swelling, but flattening of the left hip. Pulse quick and thready; profuse perspirations; loss of appetite; constant vomiting; and great emaciation. The pain in the left hip and knee was so severe that she would not allow anyone to approach the bed for fear of their touching the clothes, and could not bear the least movement of the limb.

I told the mother I could give her child immediate relief from pain by laying open the hip-joint—an operation I had performed several times with complete success; at the same time, as I believed I was the only surgeon in the habit of adopting this mode of treatment, I should wish her to ascertain the truth of my statement, and referred her to the parents of two children upon whom I had operated under similar circumstances. If she desired me to attend the child she was to let me know.

Jan. 6th.—I received a message, stating that "she placed the child under my care; I must do what I thought best."

7th.—With the assistance of Dr. Vaudin, I made an incision about four inches long, on the upper and posterior edge of the trochanter, cut down into the joint, and freely divided the capsular ligament. The upper and outer edge of the acetabulum was in a state of caries; the head of the femur seemed sound. I passed a pledget of lint dipped in oil into the joint, filled up the wound with lint, and gave her an opiate.

8th.—The child has passed a quiet night; slept well; no perspiration; a little smarting pain in the wound, but can bear the limb moved. I had great difficulty in persuading her to allow me to touch it on account of the great pain she has hitherto suffered.

9th.—On removing the bandage the pledget of lint came away. The discharge was slight, but very offensive, that of necrosed bone. I ordered her tonics and nourishing diet. In a few days sleep returned, the vomiting and perspirations ceased, but the appetite was very delicate for some time. In a fortnight she was able to be removed without pain to the sofa.

I kept the wound open by introducing a piece of lint dipped in a solution of sulphate of copper and then dried.

In two months the offensive odour of the discharge had completely disappeared, and she was able to move about on crutches. I still kept the wound open.

Jan. 5th, 1875.—The child is now quite strong, healthy, and plump. The limb is about an inch shorter than the other; she can bear her weight on it, walks very well with crutches, wearing a high-heeled and toed boot.

I consider early incision into diseased hip-joints the treatment of common sense. When the bone is diseased a quantity of acrid matter is collected in the acetabulum, the head of the femur becomes dislocated, and the tension of the capsular ligament produces intense pain in the hip and knee. This is not occasioned by the pressure of the head of the femur in its new position, as the suffering vanishes when the joint is opened. I have always found that after opening a joint with caries of the bone the healing process commences in a fortnight or a month. I cannot understand the objection of many surgeons to laying open diseased joints; it is more requisite than in a common abscess. In the latter the matter soon finds an exit, but in joints the acrid fluid is pent up, and seldom points until the whole surface of the bone is diseased.

In the year 1849 I first tried this treatment in the Nottingham Hospital; it was so satisfactory that in 1850 I operated on two private patients with equal success. On account of ill-health, I sent in my resignation as surgeon to the hospital, came to Jersey, and did not practise for some time. I have operated eight times in Jersey, and in two cases, aged eleven and thirty-nine, have after the operation succeeded in reducing the dislocations, effecting a complete cure, the patients being able to walk as well as ever.

I have been present at a great many operations for excision of the joints, and I firmly believe that were incision of the joints performed at an early stage in the disease such operations would never be required. Were it for nothing else but the immediate relief of pain produced by incision, I should recommend its adoption.

Les Creux, St. Brelade's, Jersey.

BENEFICIAL USE OF JABORANDI IN CASES OF DIABETES INSIPIDUS OR POLYDIPSIA.

BY T. LAYCOCK, M.D.,

PROFESSOR OF THE PRACTICE OF PHYSIC AND OF CLINICAL MEDICINE, UNIVERSITY OF EDINBURGH.

(*Reported by* J. M. BROWN, M.B., *and* F. ALSOP, M.B.)

THE following case of polydipsia was the subject of a clinical lecture by Dr. Laycock during the last winter session, in which he pointed out that the disease in both forms of diabetes and in certain kinds of Bright's disease and dropsy is a *neurosis*, having its seat in that part of the encephalon which regulates the amount of water in the blood, and having, therefore, both anatomical and functional relations with the sudoriparous glands and the kidneys, and with the appetite for water and the sense of thirst. The pathology and clinical history of both kinds of diabetes were discussed, and the experiments of Claude Bernard and others, as to the production of polyuria, albuminuria, and glycosuria by injury of certain portions of the floor of the fourth ventricle, were alluded to as having a distinct relation to the study of those diseases clinically.

CASE 1. (Reported by J. M. Brown, M.B., class-assistant to Professor Laycock.)—Wm. K——, aged forty, a shoemaker, was admitted to the Edinburgh Royal Infirmary Dec. 24th, 1874. He complained of great thirst, a feeling of pain and heat from the lips to the stomach, profuse urination, and a tendency to pass water frequently; also of dimness of vision.

His previous health had been good until about five months prior to his admission. During these five months he had suffered much from thirst, which was most severe at night and in the morning. He had a hard chancre many years ago, but no other personal indications of syphilis subsequently. His wife had consecutively seven still-born children. As to his social history, he had drunk considerably of whisky, having a bout of drunkenness, lasting for several days, about every three weeks.

Condition on admission.—He is a slightly-built man, 5 ft. 4½ in. in height, and weighing 8 st. 4 lb. The integument is hard and dry; temperature 98°. He stated that he did not think he had perspired for five months. The circulatory and pulmonary systems gave normal results, with the exception of a little emphysema of the anterior margins of the lungs. Pulse 92; respiration 16. The tongue somewhat furred, but at the anterior part of the dorsum a small patch is seen, about the size of a threepenny piece, denuded of epithelium, and appearing raw and glistening. The fauces are slightly congested, but quite moist. The appetite is impaired; bowels are regular. Hepatic and splenic dulness normal. He has sometimes to micturate every half-hour. The urine is pale, almost colourless, faintly acid, sp. gr. 1005; chlorides; phosphates and urea only in small amount; traces of indican; no sugar or albumen, and no organised or crystalline deposits: in short, it exhibits only the character of a very dilute urine. The testicles are rather small. He states that he has occasional nocturnal emissions, and feels competent for sexual congress. He sleeps well, and is intelligent. Cutaneous sensibility unimpaired. On examining the right eye ophthalmoscopically, the optic nerve was found to be atrophied.

The quantity of urine passed daily during the first week after admission was as follows:—

From 3 P.M. Dec. 24th till 3 P.M. Dec. 25th, 420 oz.
„ „ 25th „ „ 26th, 500 oz.
„ „ 26th „ „ 27th, 300 oz.
„ „ 27th „ „ 28th, 400 oz.
From 3 P.M. Dec. 28th till 3 P.M. Dec. 29th, 400 oz.
„ „ 29th „ „ 30th, 330 oz.
„ „ 30th „ „ 31st, 400 oz.

The patient was ordered a good diet, with two pints of milk daily, and as much ice as he chose to take with his liquids. He also took ten minims of dilute sulphuric acid and ten minims of tincture of opium every four hours. This mixture was continued till Jan. 4th, when the amount of urine in twenty-four hours was 366 oz. No good having resulted, twenty grains of iodide of potassium and a quarter of a grain of extract of belladonna were ordered thrice daily. On Jan. 15th it was observed that there was a certain periodicity as to the quantities of urine passed daily, as the following statement shows:—

Jan. 11th to 12th, 228 oz.
„ 12th to 13th, 272 oz.
Jan. 13th to 14th, 200 oz.
„ 14th to 15th, 366 oz.

Five minims of liq. arsenicalis were given along with the iodide. The patient was desired to take as little fluid as possible. He became very fond of the iced milk and water, and was sometimes observed to drink it ravenously. A warm-water or hot-air bath was sometimes administered, and on one occasion the latter induced a slight cutaneous transpiration, limited, however, to the thoracic and axillary regions. This treatment was continued till Feb. 2nd, the quantity of urine daily passed varying from 256 to 356 oz., and the specific gravity from 1005 to 1007; chemical characters as before, except that no indican was discoverable.

During the preceding period he occasionally complained of pain in various parts of his abdomen, back, and under the nipples; these pains were generally relieved by mustard epithems, or friction, sometimes assisted by a carminative. The intestines were on those occasions often inflated, and splashing sounds could be produced by slight manipulation of the abdomen. On Feb. 2nd he was ordered three grains of freshly prepared extract of valerian in pill thrice daily; on Feb. 8th, two pills thrice daily; on Feb. 10th, three pills every four hours. On Feb. 11th he had taken fifteen pills, and felt sick and depressed. On the 14th he took no valerian pills, but from the 15th till the 26th he took six pills daily. The quantity of urine passed during the period the valerian was administered diminished pretty steadily from 308 oz., sp. gr. 1008, on Feb. 4th and 5th, to 240 oz., sp. gr. 1010, on Feb. 15th and 16th. From this date (the valerian being omitted) till Feb. 26th it steadily increased to 300 oz.

On Feb. 26th the patient was still complaining of great thirst, and the skin was dry. Jaborandi was then ordered in the form of infusion of the strength of one drachm of the leaves and twigs to six ounces of water; of this a dessertspoonful was taken every four hours. On Feb. 28th a tablespoonful of the infusion was given every three hours; on March 1st a tablespoonful every two hours; March 4th, two tablespoonfuls every hour. On March 5th the skin of the back, abdomen, and inner aspect of the thighs was found to be perspiring pretty freely. On the 6th (the jaborandi being continued as when last mentioned) the skin of the arms and of the left palm perspired.—15th: The quantity of urine has declined steadily from 300 oz. on Feb. 26th to 236 oz. on March 14th.—31st: The treatment with the jaborandi having been continued, the quantity of urine passed to-day was 180 oz. The patient has found his mouth uneasy several times, and the amount of the infusion to be taken (varying from one to two tablespoonfuls every hour) is left to his own sense of comfort or discomfort. His skin is moist, and he declares himself much easier and better in all respects, but still has "some of the old burning feeling in the throat and gullet."—April 2nd: The sense of discomfort in the mouth amounts to-day to pain in the teeth and some slight difficulty in opening the mouth. He is ordered to take the jaborandi less frequently.

The quantity of urine continued to diminish steadily till the middle of May, when it amounted to 120 oz. per diem. His mouth also had become moister. The patient was then, at his own request, discharged.

The measurement of the urine in this case was most carefully conducted by the patient and nurse, and latterly by the patient alone, as he became more interested in the progress of his own case. The measurement of the liquids taken was more difficult, and was at first erroneous for obvious reasons, so that the discrepancy between the amount taken and the amount passed was great; but as the thirst diminished, and the man became in earnest as to the measurement of the fluids taken and urine passed, there was seldom more than 20 oz. difference between the one and the other.

CASE 2. (Reported by Fabian Alsop, M.B., resident physician, University Clinical wards.)—William W——, aged thirty-five, a clerk, was admitted to the Royal Infirmary, Edinburgh, under the care of Dr. Laycock, May 29th, 1875. He complains of passing a large quantity of urine, and of a desire to pass it frequently. Also of great thirst, and that he feels inclined to drink a great quantity of water at a time. The water he drinks appears to him to have a sweet taste, especially when it is cold. Patient says that these symptoms commenced nine years ago, during an attack of what the doctor who attended him termed "rheumatic fever." He says that he drank as much water then as he does now. Twelve years ago he had a swelling in the groin after connexion with a woman who would have been likely to communicate infection to him; and five years ago had the venereal disease, for which he was admitted to the infirmary, and, whilst in hospital, had his left testicle removed, and was dismissed cured. Two years after this he was readmitted, and was treated (patient says) for pneumonia. Three months ago a small papule formed at the back of his right thigh, which was not attended to, and which ended in a small ulcer about six weeks ago, and has not yet healed. Ever since his testicle was removed patient has been subject to severe frontal headaches and a feeling of giddiness, which come on him occasionally. His father and mother both died, he states, of consumption; otherwise the family history is satisfactory. He has had a comfortable home and always been well clothed, but has been given to sexual excesses and frequently has been "the worse of drink."

Condition on admission.—Patient is somewhat emaciated, and below the average development; height 5 ft. 6 in.; weight 8 st. 7 lb. His muscles are small and rather flabby. He can lie easily in any position, and is not confined to bed. He has a somewhat anæmic aspect, but his expression is natural. Temperature on admission 97·6°. Skin very dry and rough. Does not perspire at all. No eruptions nor tumours on body. There is a small ulcer, about the size of a florin, on the posterior aspect of the right thigh, with a greyish surface, and which discharges a small quantity of fetid pus; otherwise his limbs are natural. Patient has to micturate frequently, having generally to rise three or four times during the night. Through the day he passes urine, without pain or difficulty, about every two hours, amounting in twenty-four hours to 158 oz.; of a very light yellow colour, much resembling the colour of hock; sp. gr. 1008, of acid reaction; contains albumen, which occupies about one-eighth of the test-tube when the urine is allowed to stand after boiling; chlorides are abundant in quantity, so also is the urea; no sugar present; no tube-casts to be discovered under the microscope. Patient's tongue is clean. He feels very thirsty, and in order to quench his thirst has to drink a large quantity of water at a time. Has a very pleasant feeling at the back of his throat while he is drinking water. His bowels are very irregular in action; some weeks being very constipated, at others loose. Viscera of of abdomen natural. Number of respirations 20 per minute. Has no cough nor breathlessness. Physical examination of lungs natural. Pulse 72 per minute; regular in force and rhythm; of fair strength; but slightly compressible. He does not suffer from any dyspnœa or palpitation. Physical examination of heart quite natural. Patient is very shortsighted. On ophthalmoscopic examination of the fundus of the eye, a large staphyloma posticum is observed on the *apparent* inner side of the optic disc; the vessels of the retina are also enlarged, and the choroid is found to be atrophied. By direct illumination the fundus is well seen; and when the observer moves his head in one direction, the retinal vessels appear to travel in the opposite direction. Patient is easily exhausted. Sleeps pretty well at night, and would rest better had he not to get up often to pass water. Occasionally he has frontal headache and attacks of giddiness.

Treatment.—The diet was as follows:—Breakfast: Porridge, milk, coffee, and bread. Dinner: Chop or steak, vegetables, broth, and bread. Tea and bread-and-butter in the evening, and milk at night.

June 2nd.—Ordered one tablespoonful of decoction of jaborandi thrice daily.

Progress of case.—The following is a daily table of the amount of urine passed and the amount of fluid taken.

Date.	Amount of Urine passed in 24 hrs.	Amount of Fluid drunk in 24 hrs	NOTES.
June 1st	158 oz.	186 oz.	
" 2nd	154 oz.*	156 oz.	Was up four times to pass urine. Bowels costive. Half an ounce of castor oil in the evening. Jaborandi commenced.
" 3rd	150 oz.	156 oz.	Bowels moved freely after the castor oil.
" 4th	120 oz.	146 oz.	Skin very dry; does not sweat at all. Dose of jaborandi increased to two tablespoonfuls. Bowels moved twice. Was up three times last night to pass urine.
" 5th	140 oz.	146 oz.	
" 6th	154 oz.	170 oz.	During night sweat a little about face and hands.
" 7th	148 oz.	186 oz.	Sweat more. Dose of jaborandi increased to four tablespoonfuls three times a day.
" 10th	100 oz.†	126 oz.	Sweat a great deal about face, but not on body.
" 18th	110 oz.	116 oz.	Sweat profusely all over his body.
" 25th	100 oz.	126 oz.	Saliva for last few days very much increased.
July 2nd	104 oz.	116 oz.	
" 8th	100 oz.	106 oz.	
" 10th	94 oz.	96 oz.	Sweat very profusely through the night. Saliva greatly increased.
" 19th	100 oz.	106 oz.	
" 22nd	98 oz.‡	100 oz.	Patient weighs exactly 9 st.

* Specific gravity 1008; albumen 1-8th; chlorides abundant; phosphatic.
† Specific gravity 1010; no sugar; albumen 1-6th.
‡ Acid; specific gravity 1010; albumen 1-10th.

These cases are interesting as showing the use of jaborandi in a disorder well known to be intractable. The action of the drug on the skin (probably through the nerve-centres) was well marked; the salivary glands were less influenced.

Edinburgh.

ON THE

TREATMENT OF HERNIA BY INVERSION.

BY J. H. THORNTON, M.B., B.A.,
SURGEON-MAJOR, INDIAN MEDICAL SERVICE, CIVIL SURGEON OF SHAHABAD.

THIS mode of treatment, though mentioned in most surgical works, has never, so far as I know, been considered on its own merits, but merely as an aid to the taxis and the other measures usually employed in the reduction of hernia. My object in this paper is to draw attention to the efficacy of inversion alone, not only in reducible hernia, but also in many cases where the rupture has become strangulated, and to suggest that a fair trial should be given to a plan of treatment which possesses so many advantages and is attended by so little risk.

The treatment of hernia by inversion consists in placing the patient in such a position as to bring the force of gravity into play to reduce the rupture. This may easily be effected by raising the foot of the patient's bed, and keeping it supported it an angle of 45°. In this posture the intestines naturally gravitate towards the upper part of the abdominal cavity, and gradually draw in the ruptured portion. It is evident, from the nature of the case, that a force acting gradually and equally from within the abdomen must be far safer and more effectual than any pressure applied externally. The use of the taxis, however carefully applied, must almost always involve some bruising of the parts, which would have an injurious effect should the attempts at reduction be unsuccessful and an operation become necessary. Sometimes violent manual pressure is employed by the patient and his friends in repeated fruitless efforts to reduce the hernia, and in such cases very serious results are likely to ensue. Contusion of the tissues, extravasation of blood, congestion, inflammation, and even gangrene of the ruptured bowel may result from violent, protracted, and ill-applied manipulation. The various other measures sometimes resorted to, such as bleeding, the inhalation of chloroform, hot baths, purgatives, enemata, cold, &c., are all liable to the objections that they are uncertain in their operation, not suited to every case, and often attended with risk. The advantages of inversion over all these modes of treatment are, that it is generally effectual, absolutely safe, and universally applicable. It can be used by any person, at any time, and in any place; and should it prove unsuccessful in effecting reduction (which will rarely be the case unless adhesions have formed) the patient is in a more favourable condition for the performance of the necessary operation than he would be after the employment of the other methods. The following case illustrates the efficacy of this mode of treatment.

A man named Dhoree, aged forty-two, was admitted into the Charitable Dispensary at Arrah on Dec. 4th, 1873, with strangulated hernia (oblique inguinal, right side). The rupture had frequently appeared before, and he had been able to return it without difficulty. On this occasion, however, he was unable to do so; and his friends, who made repeated attempts to reduce the hernia, were equally unsuccessful. The result of their interference was that severe pain set in during the night, and, finding him getting worse, they brought him to the dispensary early in the morning. The assistant-surgeon saw him, and endeavoured to reduce the rupture by the taxis, with the assistance of chloroform; but his efforts were unsuccessful. I saw the patient at 9 A.M. about thirty hours after the appearance of the rupture. He was in great pain and distress, the bowels had not acted since the hernia appeared, there was much prostration, and hiccough and vomiting had already set in. I ordered the foot of his bed to be raised and supported at an angle of 45°, and I directed that he should be allowed to remain in that posture, and that no further attempts should be made to return the rupture. The result was that in about twenty minutes the hernia disappeared, reduction having taken place spontaneously. The patient speedily recovered. In this case the taxis, aided by chloroform, had failed, urgent symptoms had set in, and inversion was tried as a last resource, failing which an operation must have been performed to save the life of the patient. The success of the treatment by inversion under such circumstances is a satisfactory proof of its value, and shows that it might be advantageously employed in most cases of strangulated hernia, before resorting to an operation.

Arrah, Shahabad, Bengal.

ST. BARTHOLOMEW'S HOSPITAL.

CALCULUS IN A GIRL THREE YEARS OF AGE.

(Under the care of Mr. Holden.)

For the notes of the following interesting case we are indebted to Mr. James Shuter, house-surgeon.

The patient, a girl aged three years, was admitted on June 2nd. She was of fair complexion, well nourished, and a native of London. She was fed at the breast until eighteen months old, since which she has had very little milk, but some beer nearly every day.

The only points of importance observed previous to admission were that (1) during the past nine months she had been noticed to cry during micturition, and to put her hands between her legs to scratch or rub herself; and that (2) her urine had been occasionally thick.

On June 10th a consultation of the surgical staff was held, and a calculus was easily felt with a sound. Opinions were much divided as to what operation should be performed, but the majority were in favour of removal through the vagina. One recommended the suprapubic operation.

On June 18th Mr. Holden examined her under chloroform, and, passing a sound into the bladder, directly felt and heard the stone; it was also felt through the rectum, its size being found to be about half an inch long and its shape ovoid.

July 2nd.—Since admission the patient has passed urine about every half-hour, giving no other notice than always crying; this was often accompanied by much straining, and by the passage of a little motion, apparently on that account. She has frequently had a pricking pain come on suddenly between the legs and at the lower part of the abdomen when she did not pass any urine. The urine is sometimes rather thick with mucus. There has been no prolapsus nor record of blood in the urine since admission. The pain has always been relieved by hot baths.

10th.—Patient being under chloroform, Mr. Holden passed his finger into the vagina and a small pair of dressing forceps into the bladder. He then seized the stone, passed a director into the urethra above the forceps, and cut through the anterior upper two-thirds of the urethra, and then, dilating the posterior third, removed the calculus in four pieces, as it happened to break under the pressure of the forceps. Its weight proved to be 23 grs., its long diameter being ⅝ in., and its short diameter ½ in. In the evening she cried very much during the passage of urine, and had much pain at the seat of operation. There has been no sickness. She has been very restless since midnight. The parts are red and swollen.

11th.—7 A.M.: Has passed urine into the bath.—10.30 A.M.: Has passed three ounces of urine voluntarily, with but little manifestation of pain. The parts look quite healthy again. The temperature has once reached 100° and the pulse 120 since the operation, from which, indeed, she now seems to have fairly recovered.

12th.—Temperature 100·2°; has no incontinence of urine.

13th.—Temperature 99·4°; no incontinence of urine, but still cries a little when she passes urine.

HOSPITAL FOR THE EPILEPTIC AND PARALYSED.

CASE ILLUSTRATING THE RELATION BETWIXT CERTAIN CASES OF MIGRAINE AND EPILEPSY.

(By Dr. Hughlings Jackson.)

Dr. Hughlings Jackson believes that cases of migraine, and certainly those in which there are ocular phenomena with one-sided sensation disorder are (that is, according to his definition of the word epilepsy) epilepsies, for he thinks that the symptoms depend on a local excessive cerebral discharge. However, he thinks that whilst the ocular phenomena and the unilateral sensation disorder are parts of the paroxysm, the headache and vomiting are post-paroxysmal symptoms. Moreover, he believes it to be most likely that the "discharging lesion" in this epilepsy is of some parts of the cortex of the posterior lobe, that it is of convolutions, or of parts of them, which are developed out of the optic thalamus. The reason for so thinking is, that these "sensory epilepsies" bear the same relation to hemianæsthesia with hemiopia from disease of the optic thalamus, as unilaterally beginning convulsions do to the ordinary kind of hemiplegia from destruction of the corpus striatum. Dr. Latham thinks that the paroxysm of migraine is owing to arterial contraction in the region of the posterior cerebral; Dr. Liveing, that there is in the paroxysm a "nerve storm" traversing the optic thalamus and other centres. Dr. Hughlings Jackson's view as to localisation will be supposed to be a compromise betwixt these two opinions. It may here be pointed out that this localisation of the "discharging lesion" in migraine accords with an old conclusion of Dr. Jackson—viz., that the anterior part of the cerebrum is the chiefly motor, and the posterior the chiefly sensory region. This speculation agrees with Ferrier's experiments. Dr. Jackson does not, however, suppose that the separation of motor and sensory regions is abrupt. The case which follows is mixed sensory and motory. Discharging lesions may no doubt be developed in any part of the cortex cerebri from front to back.

Whether the word epilepsy be used in the commonly accepted sense or in the novel sense, the case here reported shows the relationship of certain symptoms of migraine to epilepsy. The hemiopia is especially interesting.

Colour development is not an uncommon precursory symptom in cases of epileptiform or epileptic seizures. It is common in migraine. In this girl's case, if her memory serves her, the colours began on the side which does not correspond to the side convulsed; one reason for thinking her account erroneous is that the transitory hemiopia was leftsided (field), as was the convulsion at its onset.

M. B——, aged sixteen, consulted Dr. Hughlings Jackson in August, 1873, having had fits for six years. She walked at the age of sixteen months, and talked very early. It is said that she had spasmodic croup at the age of ten months. She was subject to attacks every winter until the age of thirteen. An attack would come on about ten o'clock at night, and last for two hours, when vomiting and relief came. What the real nature of this illness may have been is matter of doubt; the mother said the girl made a noise like croup, and imitated the noise of laryngismus stridulus very closely. At the age of three years it seems clear that she had a bad attack of jaundice; she was, her mother averred, delirious and insensible for two or three weeks. She had never had scarlet fever nor rheumatic fever; she had had measles, chicken-pox, and whooping-cough. No facts bearing on hereditary tendency to any kind of nervous affection were obtained.

She seemed to be in good health. She had begun to menstruate at the age of twelve and a half years, and for the last twelve months the catamenia had been regular. There was no heart disease; there was no ear affection, nor had there been any. She had threadworms.

It is interesting to note that there was a clear account of gradual development of her seizures. She had at first attacks of coloured vision only for some months before anything further. There is circumstantial evidence of this. Her mother thought the child was bilious, and waited until her holidays began to give her physic. Further evidence that these mere attacks of coloured vision were really rudimentary or incipient fits was that later on she occasionally had these attacks, sometimes followed by convulsions, sometimes not. As she says, "if the colours do not leave, the fit comes on." After having several attacks of coloured vision only, she would have a severe fit. The colour began suddenly. There were red and green. The red comes first and the green was underneath the red. The background was black and the colours moved fast. Her mother said the girl always *looked to the left* when the colour appeared. This is significant, because "when the colours do not go away," and when the full fit comes, the head turns to the *left*, the *left* hand shakes, the arm works; there is *left*-sided convulsion. Later there is convulsion of the right side, and she is unconscious; occasionally there is tongue-biting. But here is to be stated further evidence as to gradual development of the fits. For some years she did not lose consciousness; the strong presumption is that at that time the convulsion did not pass beyond the left side, the side first convulsed; moreover, in some seizures, when she was under Dr. Hughlings Jackson's care, she did not lose consciousness, even when the fit was so severe that the left arm was invaded.

She is certain that the colour began in the *right* side of her field of vision, and spread to the left. Moreover, some years before—no accurate date could be given—she had transitory hemiopia before the fits, but never immediately before. She might, for example, see "half a face" at breakfast-time, and have a fit in the evening, but then in the interval the "colours would keep coming and going." According to the mother, the child could see to the right when hemiopic—that is, the left was the blind field. On one occasion she, over a period of a few days, occasionally saw on the left side an object of about the shape and size of an octavo page, dotted all over with rounded dots closely set. This was, she said, "instead of the colours."

ROYAL INFIRMARY, EDINBURGH.

CASE OF EXTENSIVE BURNS OF LOWER EXTREMITIES; RECOVERY.

(Under the care of Mr. Joseph Bell.)

For the notes of the following case we are indebted to Mr. Holland J. Cotton, late house-surgeon.

James M——, aged thirty-four, was admitted Nov. 28th, 1874, suffering from very extensive burns on the legs, which he had sustained ten days previously (along with a fellow-workman, to whom the injuries rapidly proved fatal), by falling into boiling oil. The patient was very haggard, and like a man of fifty in appearance, complaining of no pain and seeming semi-comatose. Mr. Bell found the right leg burnt all round, from the instep to the middle of the thigh; the left burnt over the instep and ankle, and all round at the knee, with intermediate large patches where the cuticle was destroyed. Large fetid sloughs were still hanging to the limbs, and on clipping off these a vast raw surface appeared, in which the cutis vera seemed altogether destroyed. Both limbs were enveloped in lint, spread with zinc ointment, as sufficient boracic ointment, from its difficulty of preparation, was not forthcoming. A very unfavourable prognosis was given, but stimulants were ordered to be administered freely, and as much nourishment as possible. At night he was delirious, and at one time sprang out of bed and rushed into the corridor, where he fell down, his legs all this time bleeding profusely. The next day he seemed worse, and Mr. Bell, though much inclined to amputate the right leg at the upper third of the thigh, finally decided not to do so, thinking that he was not in a fit state for operation, and hoping that, if he did rally, the cutis might prove not to be so wholly destroyed as it appeared. The limbs were in a very peculiar condition, being covered with a layer of very fetid matter, but no healthy pus forming. He complained of little or no pain when they were dressed, which further seemed to indicate that the whole thickness of the cutis vera must be destroyed. The amount of stimulants and food was increased, whilst full doses of nepenthe at night were found to be the best to procure sleep. The next few days he remained in a most critical condition, bleeding occurring two or three times from the bowels, and delirium returning occasionally at night; but, on the whole, he seemed to be improving, his appetite being especially good. A week later he was out of danger, and the limbs began to look more hopeful, a healthy granulating surface having appeared, and a copious formation of laudable pus being established, whilst here and there islands of skin began to appear, more especially on the left leg.

The next three weeks were marked by rapid progress, the patient's appearance improving daily, looking at least ten years younger than on admission. His appetite was ravenous, and he seemed to be gaining flesh steadily. The left leg went on healing rapidly along the healthy edges, but the right still remained a vast suppurating surface, although the islands of cutis that had appeared increased daily in size. It still seemed as if sufficient skin could not be formed, and that extensive skin-grafting would have to be resorted to, but in a month or more the left leg had healed completely, and the right was skinning slowly over. No other dressing was used in this case but zinc ointment until about this time, when stimulating lotions had to be used, in order to check the granulations which became exuberant and weak, after which healing progressed so satisfactorily that skin-grafting was not resorted to. The patient found great difficulty in bending his knees or extending his feet from the extraordinary amount of contraction and cicatrisation which had occurred, but he became stout and strong (when allowed to take a little daily exercise), and was finally dismissed on April 1st with both his legs healed up, and able to walk very well with the help of a stick.

In the Punjab small-pox is again prevalent; nearly 600 deaths were registered in one week from that disease. Peshawur has suffered heavily, the inhabitants of the city having a strong prejudice against vaccination—a prejudice not shared in by the Mussulman population of other portions of the province. The total death-rate in one town lately reached the enormous figure of 70 per 1000 annually.

Reviews and Notices of Books.

Lectures on Diseases of the Respiratory Organs, Heart, and Kidneys. By ALFRED L. LOOMIS, M.D., Professor of Pathology and Practical Medicine in the University of New York. pp. 549. New York: W. Wood and Co. London: Sampson Low, Marston, and Searle. 1875.

THE publication of this work, as of so many others that have recently appeared in the United States, testifies to the growing importance and originality of the medical literature of that country. A few years ago the publishers of New York and Philadelphia supplied little else than reissues of English works, and translations (many of them highly creditable and valuable) of important French and German writings; while the number of truly indigenous productions was indeed small. Now, however, our Transatlantic brethren are showing, by their vigorous and frequent contributions to medical science, that they can claim worthy place among standard authors.

The present work does not, however, profess to be original. It consists of more than forty lectures of a course on Systematic Medicine, which, the author tells us in the preface, "are offered as they were phonographically reported" at the time of delivery. They thus form a valuable text-book of the important diseases of which they treat, and as such they must be regarded, rather than as original memoirs. Viewed, then, from this standpoint, the book takes a very high rank among educational treatises, while at the same time it abounds in much original matter, especially as regards practice; and it affords, on the whole, an admirable example of a clear and concise exposition of the present state of knowledge in this department of medicine.

It will be enough if we here confine ourselves to noticing some of the more salient features of the work, since it would be impossible for us, within proper limits, to follow the author through the wide range of affections that he here discusses. We may note at the outset that, of all drugs, Dr. Loomis seems to have most faith in quinine, chiefly on account of its antipyretic powers. But he gives it also on other grounds, since he considers it most efficacious in acute catarrhal laryngitis in large doses—namely, as much as twenty grains a day to a child three years of age. Indeed, he is, happily (for in this sceptical age such faith is sadly needed), a great believer in the efficacy of drugs, of which he does not stint the dose; and at times we find him going counter to time-honoured prejudices in regard to the freedom of their administration, as will be seen later on, but never, be it said, without fully justifying his course of action.

In a book which is in the main characterised by clearness of thought and diction, it is somewhat lamentable to find in one chapter considerable ambiguity. Thus, in the lecture on Acute Croupous Laryngitis, the author shows that he, at least, is no convert to the doctrine of the identity of croup and diphtheria, while yet his very description of the former makes it difficult for the reader to know where the line between these affections is to be drawn; a difficulty which is not removed when he turns to read what is written concerning their differential diagnosis. Thus, Dr. Loomis says that acute croupous laryngitis attacks chiefly delicate, weakly, ill-nourished children, rather than strong, healthy ones, and that it sometimes "complicates diphtheria." The first of these statements is directly contravened by many authorities in this country, while the second makes the complication more complicated, and adds to the confusion of the reader. But he further says that "very frequently membranous pharyngitis precedes and accompanies croupous laryngitis" (p. 17); and again that "the most important fact connected with its clinical history is that in a large proportion of cases, before the urgent symptoms come on, the membranous exudation can be seen on the tonsils. In nine cases out of ten, the membrane is first formed on the tonsils, or in their immediate vicinity; when seen, the diagnosis is established before the urgent symptoms are developed" (p. 19). Then, acknowledging that diphtheria involving the larynx may be mistaken for croup, he says the distinctions are based upon the epidemic or contagious history of diphtheria; the constitutional symptoms preceding the throat symptoms, the enlargement of the glands at the angle of the jaw, and the laryngeal symptoms in diphtheria not being urgent; finally adding that the pharynx presents diphtheritic appearances before any laryngeal symptoms are present—a statement almost stultified by the preceding description of the onset of croup. Verily, what with "croupous pharyngitis" and "diphtheritic laryngitis," it would seem that the clinical features of these two affections are as indistinguishable as their anatomical. But this is not the time or place to discuss this still burning question, which involves so many articles of faith in medicine, and we gladly pass from it to other portions of the volume before us.

The subjects of neurotic affections of the larynx, asthma, whooping-cough, emphysema, and bronchitis, are ably treated. Then follows an admirable account of Pneumonia, lobar and lobular, the morbid anatomy of which, as indeed of all the diseases discussed in the book, is fully detailed. The author makes the somewhat startling statement, that *idiopathic* pneumonia is rare, and endeavours to show that in the vast majority of cases there is some inherent tendency to pulmonary disorder, even where the attack is to be attributed to exposure to cold. His remarks on treatment are sound and judicious. Bleeding he deprecates, even in the most sthenic forms, as tending to retard convalescence and to increase the subsequent dangers of the disease; it should only be resorted to when there is engorgement of the heart and evidence of sudden pulmonary congestion and œdema. He also deprecates any routine treatment, and strongly upholds the administration of quinine in large doses as a means of shortening the febrile stage and hastening resolution.

His remarks upon the indications for the performance of paracentesis in pleurisy with effusion, and the details of the operation, are well worthy of note. He advocates early aspiration, and the cessation of the operation as soon as any feeling of discomfort is experienced by the patient, even though this may necessitate a second tapping in a few days' time; the like rules governing the operation in empyema, where he advises repeated tappings at frequent intervals. Free opening into the pleura in empyema is discountenanced unless the purulent accumulation be too great to admit of its removal by the aspirator, save at too frequent intervals, or unless it depend upon the pyæmic state.

Perhaps, however, the best chapters in the book are those devoted to Phthisis, which from its anatomical side is one of the most difficult subjects to treat in these days of advanced histological research. Although inclining to the belief that tubercle is simply of inflammatory nature, the author thinks all the varieties of phthisis may be fairly included under the three heads of catarrhal, fibrous, and tubercular, each of which may be mingled with the other. The chief form is the catarrhal, and its main distinctive feature is its origin in bronchitis; while from the side of morbid anatomy peribronchitis is the most constant feature of each of the groups. From a description of the morbid anatomy of these forms of phthisis he passes to discuss their etiology, which he divides into general and local. Under the head of general causes he classes heredity or acquired feebleness of constitution, anti-hygienic influences, and climate; under local, bronchitis, pneumonia and pleurisy, and mechanical irritants. One passage from the first of these heads is worth quoting:—

> "Let a healthy child, during its infancy and early childhood, be subjected to the influences of small, badly-ventilated apartments, improper diet, and all the other attendant anti-hygienic influences of the tenement-house population of great cities, and it will become an enfeebled child, so that if it reaches the years of maturity it has stamped upon it a vice of constitution which is ready upon local excitement to develop pulmonary phthisis. Among the lower classes, almost the entire population of this city is stamped with this influence, and whether hereditary tendency, in the common acceptation of that term, is or is not present in this class of persons, they are exceedingly liable to the development of phthisis."—p. 228.

The symptoms of phthisis are then treated *seriatim*, together with the physical signs, the differential diagnosis between the disease in its different forms and allied affections terminating its clinical history. Under the head of Treatment there is much judicious advice. Again quinine is held to be of the greatest value, especially when there is much fever, and given in full doses at the times of febrile exacerbation. Opium, as a means of allaying cough, should be deferred as long as possible, on account of the digestive derangement following its use; and for the vomiting of phthisis, small quantities of raw scraped beef, taken in a sandwich at frequent intervals for forty-eight hours, is held to be the best remedy. After dealing with hygienic treatment, he passes to the question of climate, dwelling upon the various resorts in the American continent specially suitable for the residence of consumptives.

We must pass over the next section of the book—that on Diseases of the Heart, with the remark that all cardiac affections are here dealt with, the chapters on valvular disease being especially worthy of note, and conclude this notice with one of the most novel features in the book—that of the treatment of Uræmia. Digitalis is advocated as a diuretic in renal disease, because of its not possessing any irritant action on the kidneys, and because of its increasing the power of the heart; as much as half an ounce of the infusion being given every three hours for twenty-four hours, or until a specific effect follows. Dr. Loomis then inquires how it may be possible to reopen the "avenues of elimination" which have been closed by the circulation of the uræmic poison in the blood. This, he thinks, is to be done by "diminishing reflex sensibility and subduing spasmodic muscular paroxysms." Chloroform inhalation has been tried, and in puerperal eclampsia with success; but there are objections to its use, since it leads to new blood changes, which are detrimental to the object in view. Such objections are not to be found in morphia, and (heterodox as it is) he states that he has followed the plan of hypodermic injections of morphia in uræmia with marked success for the last seven years.

His conclusions we give in his own words:—

> "1st. That morphine can be administered hypodermically to some if not to all patients with acute uræmia without endangering life.
>
> "2nd. That the almost uniform effect of morphine so administered is, first, to arrest muscular spasms by counteracting the effect of the uræmic poison on the nerve-centres; second, to establish profuse diaphoresis; third, to facilitate the action of cathartics and diuretics, especially the diuretic action of digitalis. . . . The rules which are to govern its administration are as yet not well defined. My own experience would teach me to give small doses at first, not to exceed ten minims. If convulsions threaten, and a small dose does not arrest the muscular spasms, it may be increased to twenty minims, and the hypodermics may be repeated as often as every two hours. It must be given in sufficient quantities to control convulsions; neither the contraction of the pupils nor the number of the respirations is a reliable guide to its administration." (p. 452.)

It is to be regretted that Dr. Loomis does not tell us what is the strength of the solution of morphia he employs. If it be that usually employed in this country (one grain in six minims), then ten minims would be nearly two grains of morphia, by no means a *small* dose. The treatment is heroic to a degree, especially as the ordinary signs of narcotism are to be disregarded. And yet he has not known a case in which death could be attributed to the narcotism produced by these measures. If Dr. Loomis be right, he will have a hard battle to fight before he makes many converts, for if any "prejudice" in therapeutics be deeply rooted it is this—that opium is contra-indicated in renal disease.

We have dwelt chiefly upon what was novel in this work, the style and character of which are deserving of all praise; and if we have left much of it untouched, it is not because there is not valuable enough matter in it, but rather that our readers may go and seek it for themselves in pages which will well repay perusal and careful study.

THE NATIONAL NURSING ASSOCIATION.

The Report of the Sub-Committee of Reference and Inquiry recently issued is without doubt the most complete and most categorical *résumé* of the entire subject that has as yet been given to the public. We have seldom perused a more able or more exhaustive treatise, and though, as we remarked before, the promoters of the Association "aim high," the class of helping hands when found and trained ought to be invaluable in this country as a direct means of restoring to health and alleviating suffering, and so averting much of the preventable misery that exists in our towns and cities.

More than nine months have been occupied in obtaining and collecting the materials for the Report, and it is proper in this place to record that the chairman, Mr. Rathbone, M.P., has liberally defrayed the entire expenses in connexion with its publication. A map is appended to the Report, which gives at a glance the ecclesiastical districts into which the metropolis is divided, and enables the reader to see the extent of district nursing done in them by both trained and untrained nurses. The poorest and most suffering districts, the name and address, the nature and professed character of the work by every nursing or nurse-training institution in the capital, are all given in detail, and in many instances the results of their experience. The clergy and medical officers of each and every district have been consulted, resulting in much information and many valuable suggestions. "The counsels of Miss Nightingale, the experience of Dr. Sibson and Dr. Sieveking, and the knowledge acquired by the secretary of the Nightingale Fund, have contributed mainly to systematise and direct the conclusions to be drawn from the array of statistical and personal testimony obtained by Mr. Guyton (the secretary), and the results of Miss Lees' close and careful visitation of hospitals and districts." After calling attention to the value of nursing, the want felt by all classes of better nurses, the necessity that nurses should be trained, the vast demand and the very limited supply, and the fallacy, practically speaking, of amateur nursing, the necessity of training schools is insisted upon in detail. In all the best training schools for nurses the subjects in which a nurse is expected to become skilful have been copied from the rules originally drawn up for the use of probationers in the Nightingale School attached to St. Thomas's Hospital. And here commences an assertion oft repeated in the report, to the effect that very few, if any, hospitals are so constructed and administered as to afford a good and wholesome field for the proper instruction and training of nurses. A great deal (and, as we think, too much) is recorded as to the present inefficient structural and administrative arrangements that obtain in the metropolitan hospitals, as to actual or implied immorality in some institutions resulting from a laxity in rules that govern the work and attendance of nurses and students, and as to the impossibility of training nurses properly under such circumstances. This by the way. "Hospital training means careful discipline and drill" as well as to "do dressings" and know how to employ surgical appliances. An efficient teaching staff, under the direction of a head competent both to teach and to control, is primarily required, and with a staff of women teachers and pupils this head must necessarily be *matron* of a hospital, independent, according to the opinion of Miss Nightingale, on the score of discipline of the medical officer or governor of the hospital. Twelve months is the time fixed by the Nightingale trustees and the promoters of the Liverpool Nursing Association as necessary to qualify a woman of average intelligence and fitness. The adoption of nursing as a profession by ladies is urged, because great need exists for a certain number of superior superintendents in dealing with district nurses among the poor. And this leads to the consideration that a higher and more thorough training than that required by hospital nurses may be necessary in private nursing even among the rich. A far greater amount of theoretical knowledge is required for out-door work, for in the carrying out of purely hospital duties, the nurse has always, as it were, at her elbow the house-physician or surgeon, means and appliances of all kinds, linen, water, and all other clinical necessaries in abundance; whereas at the best appointed private house some of these requisites are wanting. The evidence of many well-known hospital physicians and health officers is quoted to show the value of district nursing, and the great demand for it. The Liverpool Training-school and Home for Nurses, which has been at work for thirteen years, shows an enormous amount of useful labour accomplished, and the same may be said of a similar establishment at Derby, which is described as "in pure nursing the most successful in its results." It appears that the Bible-women nurses, bodies of whom are employed in the eastern districts of London, are insufficiently trained, being taught to regard their nursing duties as subordinate to spiritual objects. There is, too, in these cases no regular communication of any kind between the doctor and the nurse, the latter not taking charge of acute or infectious, but only of chronic cases. As to the actual nursing in London at the present time, it appears that in district work there are about one hundred nurses engaged (and this among a population of three millions and a half), one-third of whom can hardly be said to be trained at all. One-half of the entire number consist of the Bible-women nurses above referred to, who receive three months' instruction of a more or less perfunctory nature in a general, and one in a lying-in hospital. Of the various sisterhoods working on a comparatively small scale, none of the nurses are considered to have received a proper amount or style of training, though their devotion to duty is beyond all praise. In discussing the best mode of compassing the professional training of nurses, the report cites that two courses appear to be open to the Association. It might establish a training school of its own in connexion with some London hospital, obtaining, by arrangement with the hospital authorities, the general control of the nursing and assistance in the education of probationers. Or it might simply obtain leave to send so many pupils into a certain number of hospitals, under these existing arrangements foregoing all responsibility for the method, and losing much of the control over the results of the teaching, but securing a regular supply of nurses trained up to the standard at present attained in the several hospitals. From the view of the Committee the former plan would of course be preferred. Reasons (somewhat, as we think, exaggerated) are given why the present hospitals in the metropolis are unfit as training schools; and it would appear, moreover, that the Middlesex, the London, St. George's, University College, King's, Westminster, and St. Thomas's are at present fully occupied with the demand made upon them. Unity of control is most strongly insisted upon, as well as the principle that the head of the training school should be also matron of the hospital, with full and sole power over the engagement, dismissal, and discipline of nurses and probationers, the hospital authorities controlling the nursing through the matron, and holding her responsible for its efficiency.

It remains to be seen whether the Association will succeed in affiliating its proposed training establishment to one of our large metropolitan institutions, or whether (as we think probable, at all events at the outset) arrangements will be made with some of the hospitals, so that when a sufficiency of trained nurses is obtained, a model district Nurses' Home, under the charge of a trained superintendent, may be established.

There are no less than twelve valuable appendices to the Report, which we are compelled to reserve for a separate notice. The Association will have our hearty support in aiming "to establish a standard for district nurses and nursing which may be applied by the Association not to London only, but eventually to all England."

ANNUAL REPORT OF THE LOCAL GOVERNMENT BOARD, IRELAND.

This, the third Report of the Local Government Board, shows that the average daily number of persons receiving relief in workhouses in Ireland for 1874–75 amounted to 47,113, whilst 30,319 obtained out-door relief, being a slight increase in both forms over that of the preceding year. The dispensary tickets issued during the twelve months were 501,027, and the visiting tickets 186,138, making a total of 687,165; whilst 139,587 people were vaccinated, and certificates given in the case of 953 dangerous lunatics. Among the patients visited were 14,424 cases of fever, 7413 of scarlatina, and 961 of small-pox. This last disease has not yet been thoroughly stamped out, no less than 142 deaths from this malady having taken place in the workhouses alone. Inoculation still continues to a considerable extent, and vaccination has decreased, but the Board indulge the hope that the greatly improved machinery for the prevention of disease provided by the Public Health Act will have the effect of inducing the sanitary authorities to exert themselves zealously and perseveringly in the performance of their duties in this respect generally, and especially for the suppression of small-pox.

But four additional midwives have been appointed since last Report, and the Board draw attention to this matter, stating that where educated midwives have not been appointed, the wives of the poor peasantry at their confinement have recourse to the assistance of some neighbouring matron or woman calling herself a midwife, who seldom possesses sufficient knowledge of midwifery to be able to say when some obstruction to the birth, admitting of easy remedy by the accoucheur, has occurred, or when the case is of such a kind that the unaided efforts of nature cannot accomplish the delivery. In cases of the former description the patients are often exposed to needlessly prolonged and severe suffering, and in those of the latter, besides similar useless suffering, the lives of both mother and child are in extreme danger by the exhaustion of the patient before manifestly approaching death warns her friends to call in the aid of a doctor. The total disbursement of poor-rates for relief, medical relief, burial-grounds, registration of births, deaths, and marriages, sanitary measures, and expenses under Superannuation Acts, was £1,001,989, or 1*s.* 6*d.* in the pound.

Medical Congress of Andalusia.—This Congress will take place in Seville from the 7th to the 13th of November, 1875, and will last a week. The office-bearers have already been chosen, and a list of them is given in the *Anfiteatro Anatomico Espanol* of the 30th of June. The nature of the subjects is as follows:—First day: Opening meeting—Medicine. Second day: Surgery. Third day: Hygiene, Physiology. Fourth day: Insanity, Forensic Medicine. Fifth day: Opthalmology, Dermatology, and Syphilis. Sixth day: Therapeutics and Medical Hydrology. Seventh day: Anthropology and subjects chosen by the members.

THE LANCET.

LONDON: SATURDAY, AUGUST 14, 1875.

THE correspondence in our columns on the relative merits of chloroform and ether as general anæsthetics indicates the deep interest the profession takes in the subject at this moment. Our object has been, and will be, to give free scope to the expression of capable opinion and full scope to the communication of knowledge. We repeat again, what we have often stated, the expression of our belief that ether is the safer of the two anæsthetics. In this respect we differ in degree only from what was said in our last impression by Mr. POLLOCK, Mr. BRUDENELL CARTER, and Mr. WARRINGTON HAWARD. At the same time, we are forced to the conclusion that there are wanting many more facts and a prolonged inquiry before it would be safe for anyone to affirm that nine-tenths, nay, probably nineteen-twentieths, of the profession throughout the world are doing wrong in not dismissing chloroform altogether, and returning to the exclusive use of ether. Before such a conclusion can be correctly affirmed, it must be shown, first, that ether is *absolutely* safe; and, secondly, that it is so much safer than chloroform, and the other rapidly acting members of the chlorides of the methyl series, that the disadvantages under which it labours are amply compensated by the greater security it confers. Unless ether can stand these tests of its superiority, it will be a second time discarded, notwithstanding the advice and instruction of those who are at present so enthusiastic in its favour, should it even again assume its position as the anæsthetic of the day.

Measured by this rule, from the experience of it that now exists, it certainly does not hold the place that has been claimed for it. To say its administration is absolutely free from danger is to make a case in opposition to evidence. We have ourselves, in conducting relative experiments with ether, chloroform, methylene bichloride, and other anæsthetic vapours, seen animals die as suddenly under ether as under the other vapours. Moreover, it is vain to deny that the human subject has died during the administration of ether, and as a result of the administration. No one can read candidly the particulars of the death of a patient on September 11th at the Hôtel Dieu, Lyons, without being convinced that the death was from ether; if that case is to be disputed, every death from a chloride may be equally disputed, and we may affirm that death during an operation under an anæsthetic is always from the operation or always from the anæsthesia, and never from the anæsthetic. The death at Southampton in 1873 seems to us, so far as the report of the facts testifies, to have been equally clear in relation to its cause. The death at the Cancer Hospital was primarily a collapse from the inhalation of ether, and, although in that instance it is fair to argue that life would have been restored if there had not been an escape of blood into the trachea, the argument, after all, is but an excuse which, applied to chloroform, would not, in the present mood of the opponents of that agent, be so readily admitted. In the early days of etherisation it was, moreover, believed that some secondary dangers from ether were not to be slighted. Mr. ROBINSON, of Gower-street, on one occasion administered ether for the operation of amputation of a lower limb, and the patient, an elderly man, never recovered the narcotism, but remained semi-conscious and restless until his death some hours afterwards. Sir JOHN FORBES, in his famous article on the Discovery of Anæsthesia, expressed his conviction that the patient died of surgical shock, and, if we remember rightly, he quoted TRAVERS on the symptoms of shock in support of his assertion. But unfortunately, Mr. ROBINSON, the administrator of the ether, did not share in this opinion. We knew him well, and his view was that the patient never recovered from the narcotism, but that he died as if he had taken opium, or had received concussion of the brain. ROBINSON, indeed, who was the first administrator of ether in England, and who was most practised in the matter of its administration, was soon so alive to danger from it that he invented an oxygen apparatus for restoring those whose lives were in jeopardy from its inhalation.

There remains the second position to which we have referred—How much safer is ether than chloroform? This question, we venture to think, can only be answered when ether has had twenty-five years of trial in every respect equal to that which has been given to chloroform. Mr. CARTER speaks of the colossal experience by our American brethren of the use of ether; but our American brethren have also had a colossal experience of the use of chloroform, and it is remarkable how small has been their experience of death from that agent. During the great war of the rebellion the surgeons of the armies, North and South, used chloroform as the leading anæsthetic. How many deaths can be adduced as from the agent in that colossal experience? At the close of the war one small metal chloroform inhaler, with nostril tubes, was brought to this country, which inhaler had been used many thousand times without a death from its employment. In the Franco-German war chloroform was the agent used most as an anæsthetic; in the Crimean campaigns it was the agent of all the armies — French, English, Russian, Turkish, — and the deaths from it were so slight that they cannot be adduced now as argument against it. We do not say this to defend chloroform, but to prove how futile it is at this time to assume a comparison from the present experience of the relative safety of chloroform and ether. It is true that Dr. ANDREWS gives a mortality of 4 deaths in 92,815 from ether, or rather more than 1 in 23,000, as Mr. POLLOCK states. But these figures are by no means satisfactory: they represent little more than the whole mortality from ether from the whole administration of it, and they are therefore based on far too limited a scale to be trustworthy. In some instances chloroform has been administered for a great many thousand times in one place or by one person without a death, and if a few such examples only were put together, as low a mortality might be assigned in relation to it. But when such figures are multiplied and repeated over long tracts of years the results vary so greatly that the first series of facts in no way answer the question that has to be decided. We mean by this that if four persons die from ether out of one number of ninety-two thousand, that is no evidence that the same number only will die out of the next number of ninety-two thousand. Against the tables of Dr. ANDREWS there is also, as we conceive, this further error, that they exclude all deaths from ether that occurred during its administration, except it is stated that the death was owing to the action of the agent, while in the statistics relating to chloroform death occurring during the administration is in every case set down, if we do not mistake, as due to the administration. There is therefore a necessity for new research on deaths from anæsthetics of every kind in order to ascertain how much evil must be attributed in each case to the condition of the patient, the operation, and the anæsthetic.

We have said enough to indicate that a great deal has yet to be learned on the whole subject of anæsthesia, general and local. We have already in previous numbers of THE LANCET reported on the history of anæsthetic discovery; and we have arranged to present in future numbers a comprehensive report, experimental and practical, on the whole question. We leave the argument at present as it stands for such modification as labour and research may supply, reserving to ourselves the privilege of commenting, from time to time, on the progress, general and local, that comes to light from every independent and trustworthy source.

◆

INASMUCH as the ministerial whitebait dinner was eaten on Wednesday, and Palace-yard is now deserted, it is a duty owing to *our* constituents to place in review the doings and events of an expiring session of Parliament, so far as they interest or affect the readers of THE LANCET. All possible materials are at our elbow, for the annual gathering has occurred and the annual speeches have been made at the Mansion House, at which hospitable establishment the Prime Minister, with accustomed post-prandial felicity, congratulated his host and the assembled guests on the work that Parliament had achieved. Mr. DISRAELI told how he and his colleagues had redeemed their pledges to the country, and, as a skilled tactician, did the business marvellously well. But let us see what, in sober truth, has been done at Westminster during the past six months.

A Public Health Bill has been introduced by the President of the Local Government Board, which was avowedly one almost exclusively of consolidation. The only new clauses were those that will, as it is believed, enable the authorities in one district to take action as to nuisances that arise in a neighbouring sanitary area. The want of some such provision has been specially felt with respect to certain noxious factories on the banks of the Thames, but the provisions included in the Bill are obviously insufficient, unless an extension of the terms of the Alkali Act is also made. There can be no doubt that this last consolidating Act will do much to simplify sanitary work, render it fairly comprehensible to the executive in urban, rural, and port sanitary districts, and show at the same time how much further legislative action is required in order to render the existing statutes workable and efficient.

The Artisans' Dwellings Act is, doubtless, in a sanitary, social, as well as political sense, the measure *par excellence* of the session. The fact, long acknowledged, that many cities and boroughs in England are so built and so densely populated that the buildings contained therein "are unfit for human habitation, and fevers and diseases are constantly generated there, causing death and loss of health," is, in the preamble of the Bill, a recital of evil sufficient to claim a remedy. The Act, which became law about a fortnight ago, applies to the City of London and the metropolis, and to urban sanitary districts in England and Ireland containing a population of twenty-five thousand and upwards, the authorities for carrying out the provisions of the Act being the Commissioners of Sewers (for the City), the Metropolitan Board of Works, and the respective urban sanitary authorities. Powers are given to deal with unhealthy areas, the medical officers of health initiating the reforms by representation to the local authority. We noted in THE LANCET of last week that the Holborn District Board of Works and the Corporation of Liverpool have already commenced operations under the Act, the effect of which will be (if its provisions are judiciously exercised) to improve to a vast extent the sanitary condition of the metropolis and of all large towns throughout the kingdom. We may remark incidentally that, as by the 12th section of the Act the Metropolitan Board of Works are empowered for this special purpose to employ a medical officer, it would be well, at all events in the first instance, to choose this officer from Mr. SIMON's staff at the Medical Department of the Local Government Board.

It is a satisfaction to report that the College of Surgeons have, tardily enough, asked for and procured an "enabling" Act, which will give them powers to take decisive action under the Conjoint Scheme. We shall wait and watch for the result next session, because, as it appears to us, another obstacle that stopped the way to the "one portal" is now removed.

The Sale of Food and Drugs Bill has again been before Parliament, and, in accordance with the report of the Royal Commission, the Act of last year has been so mutilated that, as we may fairly say the last end has been worse than the first. It does not, however, seem to us that any special objections need be taken to nominating the authorities at Somerset House referees in all cases of antagonistic evidence, if the laboratory department is sufficiently well officered.

A Pharmacy Bill for Ireland has also passed both Houses, and will shortly become law.

The Select Committee appointed to report on the now notorious Hampstead Hospital question has decided that there is no reason why, in such a case, this particular district should claim the interference of Parliament.

The medical officers of the army are to be congratulated on the energetic way in which their grievances were put before the House by Dr. LUSH some two months ago. He remarked emphatically on the want of a healthy flow of promotion through the department, on the arbitrary manner in which officers were removed from their regiments, and on the general uncertain position that they hold in the service.

In the "massacre of the innocents" are included the Medical Act (cleverly staved off by Lord SANDON), the Rivers Pollution Bill, and Mr. CHARLEY'S Infanticide Bill,—all of special importance to the members of our profession and to those interested in the sanitary condition of the people. Two Bills referring to Vivisection were introduced by Lord HENNIKER and Mr. LYON PLAYFAIR respectively, but were withdrawn on the appointment of a Royal Commission on the subject, the report of which Commission has not yet appeared. We cannot affect to regret, on sanitary grounds, the collapse of the Merchant Shipping Bill, because all new provisions relating to the health of seamen were in it utterly and entirely ignored. Opportunities were afforded for improving the condition of our sailors by instituting a medical inspection before signing articles, and by various other minor provisions; but, as it would appear, Mr. PLIMSOLL'S pertinacity as to unseaworthy ships has blinded the Government and the public to the existence of unseaworthy sailors. A crude and ill-considered measure, called the Mercantile Marine Hospital Service Bill was introduced into the House by Captain BEDFORD PIM, but did not reach a second reading. The same member, however, obtained an important return relative to ship surgeons, which showed a list of more than 200 unregistered practitioners serving in the mercantile marine; 8 of whom were only twenty, and 6 nineteen years of age! So much for the sanitary supervision of the Board of Trade.

In conclusion, we cannot congratulate the Government on the termination of the session. *Sanitas sanitatum, omnia sanitas,* was a very good war cry; but we were bound to expect from a Ministry that adopted it as its motto a little more energy and practical workmanship in things relating to the health, and therefore the prosperity, of the people.

◆

WE have always maintained that one of the great uses of the British Medical Association is that it creates once a year an occasion and an audience, when and to which authoritative accounts can be given of the state of the different branches of the science of medicine, and mainly of medicine itself, as comprising a scientific investigation into all that constitutes disease and the treatment of disease. This duty in the present year was devolved with great propriety on Dr. J. WARBURTON BEGBIE. Many of the readers of his address will be disposed to think that he might have disregarded the question put by the late Sir WM. HAMILTON—Has the *practice* of medicine made a single step since HIPPOCRATES? It is true that this question was put by the illustrious professor so far back as 1832. But even then there was a certain look of ungraciousness about it. Vaccination had been discovered; chinchona and the alkaloids had been introduced into practice; and the marvellous significance of atmospheric impurities, especially in hospitals, had been indicated half a century before by Dr. CLARKE'S discovery of the remarkable effects of fresh air in abating the mortality of newly born children in the Dublin Lying-in Hospital—a discovery which is not sufficiently appreciated even in this age of hygienic medicine. LAENNEC had introduced auscultation—not, however, without candidly pointing out that he had found a passage in HIPPOCRATES which showed that he in a way used immediate auscultation. If Sir WM. HAMILTON had fully considered the significance of such discoveries as the above in the light of the unrivaled learning which he possessed, he might have framed his question in less ungracious-looking terms. Still, there was enough of antiquity about the chief parts of medical practice when Sir WILLIAM'S question was framed to make it not altogether unreasonable. The further point remains: Allowing that Sir WILLIAM'S question was not altogether unreasonable in 1832, was there any justification for Dr. BEGBIE seriously reviving it in 1875? Be this as it may, he had an easy task, and would have had a still easier one if he had not spent a large portion of his address in magnifying, not unjustly, the wisdom of HIPPOCRATES and the excellence of his practice. Most of us would have been well pleased if Dr. BEGBIE had given us more numerous illustrations of the great strides of modern medicine. But it was more magnanimous and more helpful to scientific modesty to keep before his hearers, as he did, the great merits and wonderful sagacity of HIPPOCRATES and of the men who in the various schools of Europe have kept the lamp of medicine burning during the darkness of intervening ages. Not only so. When we consider what has been done since 1832 in the way of improving the practice of medicine, we are struck with two points: first, that the curative agency or tendencies of nature are more clearly recognised; and, secondly, that where Medicine attempts to interfere, she does so with a preference for milder and less perturbative means than were in fashion up to the time of Sir WILLIAM'S question. And in both these respects there is a reversion to Hippocratic ideas. There is no part of Dr. BEGBIE'S praise of HIPPOCRATES which is more just than that in which he praises the Father of Medicine for his admirable rules for preparing fomentations for the relief of the pain of pleuritis. Of late years, fomentations and poultices have been deservedly preferred, in inflammations of the chest as in other inflammations, to blisters and irritating applications; and the due description of their merits has yet to be written.

But Dr. BEGBIE, though magnanimously enlarging on the old medicine, amply vindicates the title of modern medicine to respect. It is gratifying to know that philosophers, whatever their theoretical views of medicine, have a great practical respect for it, and readily betake themselves to those who practise it. We see no proof of abatement in any class of society in its faith in medicine coinciding with its greater ability to criticise it—not merely medicine in the abstract, but in medicines themselves. What wonderful words are those of LIVINGSTONE in which he describes his servants forsaking him and taking away his few goods and chattels, including his stock of flour—"*but the medicine chest was the sorest loss of all!* I feel as if I had now received the sentence of death like poor Bishop M'KENZIE." Medicine can bear the reproaches of philosophers when the value of its mere instruments is thus attested by a man contending with the deadly influences of Africa. Dr. BEGBIE vindicates modern medicine, not only for the means it employs, but for those it has abandoned. He rightly, though withal modestly, lauds its scientific basis in anatomy and physiology; its particular discoveries, especially that of anæsthetics; that of the uses of particular drugs, as of bromide of potassium in epilepsy, of iodide of potassium in aneurism, of cod-liver oil in phthisis, of the value of cold as a remedy in hyperpyrexia, of the similar power of quinine, of the use of turpentine in hydatids of the lung, &c.

How just is Dr. BEGBIE's praise of ALISON, who in his own philosophic way indicated the two lines of inquiry by following which Medicine, in his opinion, was to be improved—as it has been improved,—first, by the discovery of specifics; secondly, by investigation into the causes of disease. Since Sir WILLIAM HAMILTON's question was put we have received the light of Dr. BRIGHT's researches into the relation of certain palpable symptoms of debility and dropsy to disease of deep internal organs, which have done more perhaps than any other to enlarge our views of the nature of organic disease. Valuable results have been effected in the way of investigating the causes of disease, and the ways in which they are propagated, such as typhoid, phthisis, &c. This may be despised as mere progressive pathology; but it is on a knowledge of this kind that a correcter, if a more modest, system of medicine is to be based. The distinctions of continued fever might have been considered to be only pathological had the great pathological distinctions not stimulated observers to a complete differentiation, including a difference in etiology, and even in their treatment. We leave Dr. BEGBIE's address with the assurance that the practice of medicine in 1832 had made a great step since HIPPOCRATES, and has taken very long strides since 1832. Though, alas! our ignorance is still great and our power very limited, life is on the whole longer and disease shorter, less painful and less uncontrolled, and life would be longer still and disease less frequent if men and States respected the accomplished discoveries of medicine more than they do.

◆

WHOEVER has a competent acquaintance with the requirements of public health administration will welcome the Right Hon. LYON PLAYFAIR's address at the opening of the Public Medicine Section of the British Medical Association in Edinburgh. Especially they will welcome his statement that what he then said respecting the vicious administration of the Public Health Laws by the Local Government Board he is prepared and proposes to sustain in his place in Parliament. Probably he is the one man alone competent to deal properly with this question in the House of Commons, and it is matter for congratulation that he has at length found time to give serious attention to the existing state of things in the administration of the Sanitary Laws. How it has come to pass that neither he nor any other member of the Legislature has before protested against that frustration of the essential objects of the sanitary legislation of 1871 and 1872 it would perhaps be idle to inquire. What considerations of ministerial or departmental etiquette or of party or of politics may have induced members of Parliament to remain silent while the whole question of public health administration was being made subsidiary to the aggrandisement of a particular section of a particular public department might be a subject of curious if not very useful speculation. But the fact will remain for the historian of the social history of the time to consider, that the Legislature having, after much delay and with no little trouble, provided for local sanitary administration on a sound technical basis—for the substitution of trained knowledge in local sanitary proceedings for the "rule of thumb" which had previously for the most part held good,—the Government Board entrusted with the supervision of the laws thus providing deliberately and of aforethought frustrated their purpose. This Board eliminated wholly from its own administration of the laws all previous technical knowledge of the subject to which they related, and it taught by precept and example (as it still teaches) that, except as to the strictly legal routine fulfilment of a specific requirement of the law, local sanitary authorities should do the same. As Mr. PLAYFAIR remarked, it placed the medical officer of health on the same footing in relation to the sanitary authority as the Poor-law medical officer stands to the Poor-law authority, removing from him at once his essential functions of preventive officer. Whatever doubt may have remained upon the minds of persons regarding so almost inconceivable a state of things must now have been effectually removed by the lately published reports of the general inspectors of the Local Government Board; and it is to be surmised that the publication of these reports first showed Mr. PLAYFAIR clearly the scandalous perversion of the essential objects of the sanitary legislation of 1871 and 1872 which had been effected by the Local Government Board. In these reports, from beginning to end, the object or aim of the Sanitary Laws is dealt with simply as the removal of nuisances, and the inspector of nuisances is regarded as the particular officer whose duty it is to prevent disease. The medical officer of health has no place in the scheme of prevention. He is dealt with solely as a resource in case the preventive efforts of the inspector of nuisances should fail—a person to be called in, like the doctor in ordinary life, to remedy disease, if the sanitary authority, on the one hand, or the central inspector, on the other, should hold it advisable. The action of this officer is to be strictly limited by the conceptions of disease-prevention held by the sanitary authority, the central inspector, and the inspector of nuisances. He is to be reserved as a rectifier of sanitary administrative blunders, as expressed in preventable sickness, just as the technical staff of the central administration is reserved for this purpose. The measure of success of local sanitary administration is the removal of nuisances, not the abatement of disease; and the extinction of nuisances is a mere matter of common observation. Mr. PLAYFAIR said that the Local Government Board had misunderstood its function by cramming common sense into boards already saturated with it, and withholding scientific sense which they cannot be expected to possess. Is Mr. PLAYFAIR justified in insulting, even though unintentionally, "common sense" in this fashion? It is impossible to maintain the species of lay inspection of sanitary administration instituted by the Local Government Board without discrediting the scientific elements of sanitary administration throughout; and the Board and its inspectors have not hesitated to do this. The result has been a species of apotheosis of "common observation," as typified by the inspector of nuisances in the new sanitary administration of the country. The compulsory appointment of medical officers of health, except as the means of inaugurating an administration founded upon the knowledge of the sickness and deaths of a locality, would not only be meaningless, but unjustifiable. The Local Government Board has not hesitated to deprive the appointment, in practice, of its proper meaning, by instructing sanitary authorities, through its inspectors, that the appointment is largely useless—*except when epidemic disease is present.* This has long been patent; but no member of the Legislature has as yet spoken of it in his place in the House, and until now none has shown an adequate conception of its importance in his extra-parliamentary utterances. It is hardly to be hoped that the Legislature can contend successfully against a thoroughly organised and powerful department like that of the Poor-law (otherwise Local Government) Board, with its administrative interests at stake. That Board has done this mischief in sanitary administration too thoroughly, thanks to the indifference of Parliament, to be remedied without long work. It has so successfully prejudiced rural sanitary administration against medical officers of health—in other words, against trained technical knowledge in its deliberations,—that the present generation will hardly unlearn the injurious teaching. Mr. PLAYFAIR touched the core of the subject when he insisted that central and local sanitary administration should be based upon audits of death and disease. He justly observed "that unless the medical officers of health are trusted by the local authorities as their immediate sanitary advisers, and are encouraged to use the knowledge of sickness and death, gathered in the locality, for the prevention of disease, local government will continue to be looked upon as an unpleasant machinery for augmenting rates, and not as one for economising the life and resources of communities."

◆

THE circumstances which were revealed at an inquest held last week in Islington are of considerable interest to the public and to the profession. The inquiry was into the cause of the death of an old Indian general, who, it was alleged, had been wrongfully detained as a lunatic. The causes of his death were sufficiently clear to satisfy the jury that it was due to natural causes. The evidence of his mental state was not sufficiently clear to satisfy his executor, and it is possible that more will yet be heard of this part of the case. The medical relations of lunacy are very important, and the bearings of this case on those relations are of more than usual significance. The deceased was seventy-five years of age, and had lived for six years in lodgings at Islington, temperate and in good health till March, when he became ill with congestion of the lungs, and was attended until the 3rd of June by Dr. SILLIFANT, in whose opinion he was sane up to that date. In the opinion of his two sons he was not sane, and by their instrumentality Dr. SILLIFANT was dismissed and the patient placed under the care of Dr. BROXHOLM, who found him, he says, dirty, taking large quantities of alcohol, talking disconnectedly, and, in his opinion, insane. The nurses were changed, the landlady denied access to him, and, after consultation with Drs. WILKS, TUKE, and MAUDSLEY, certificates were signed by Dr. BROXHOLM and Dr. TUKE, and he was committed to the charge of a male nurse, JOHN WHEELER, who had been placed in the house. The order committing him to the charge of WHEELER, signed by one of the sons of the deceased, contained the manifest inaccuracy of intimating that the house in which he was to be kept was that of the attendant, when it was, in fact, that in which he had been living for six years. It would appear also that the patient remained under the care of Dr. BROXHOLM, who had signed one of the certificates of lunacy. On the mental state of the deceased much contradictory opinion was expressed. It cannot be imagined that Dr. TUKE or Dr. BROXHOLM would have signed the certificate unless distinct and sufficient symptoms of insanity had been obvious to them; but the report of the inquest does not give details on the point full enough to enable an opinion to be formed. In the judgment of the executor, Mr. LOWE, of Parliament-street, who knew him well and saw him frequently, the General was throughout perfectly sane; and Dr. LANGSTON, who accompanied Baron CLEASBY to see him the day before his death, was of the same opinion, as, it would appear, was also Dr. WILKS on the 26th of July.

The details of the case illustrate very forcibly the need for extreme caution in dealing with those supposed to be insane. Their management, the circumstances in which they are maintained, should be above the suspicion of injustice or of injury. However common may be the practice of ordering a lunatic into the entire charge and control of an attendant, we cannot but think that it is one most undesirable, and to be avoided whenever possible. It should be always foremost in the mind of those who have to order or sanction the arrangements for the care of the insane that the object of restraint is their recovery, no less, but more, than relief to their friends; and the means employed should always be those most calculated to further restoration to health of mind as well as of body.

Annotations.

"Ne quid nimis."

OVARIAN AND UTERINE PATHOLOGY.

THE address of Dr. Matthews Duncan at Edinburgh, as President of the Obstetric Section of the British Medical Association, magnifies the importance of the ovaries and their diseases as factors in producing the ailments of women. The greater ease with which lesions and malpositions of the uterus can be detected has, he seems to think, led to an erroneous estimate of their frequency and importance as compared with ovarian lesions. His remarks on the common and superficial lesions of the cervix and on the stereotyped treatment of them we reproduce in their entirety, as well as his observations on the pathology of the inner surface and body of the uterus:—

"The application of physical methods to the investigation of the diseases of the genital organs brought to light, first, the most superficial or most easily observed of uterine lesions—the ulceration, as it was called, of the cervix; and it was inevitable that to this great importance should be attached, an importance far beyond what it really possesses. This importance has now, for at least a decade, been rapidly declining; and while it is admitted that the lesion is very significant, and forms an element of the most common

> disease of women, it is now well known that it has been not only exaggerated in importance, but misinterpreted as to its relation to the discharge; and that the treatment, by applying lunar caustic through the speculum to the visible ulceration, once so very widely used, is only rarely a good or successful method. Great improvements have recently been made in the theory and treatment of diseases of the neck of the womb; but we can only say that great and admirable attempts have been made to improve in a similar manner the theory and treatment of the analogous diseases of the body of the organ. Endometritis, even, is very inadequately described; and the attainment of this is, or should be, our first step to knowledge of disease of the uterine body. The influence of displacements and their relation to uterine congestion are not settled matters, after all the voluminous writing which has been zealously devoted to them."

The above remarks show clearly that Dr. Duncan does not mean to advocate the neglect of the uterus, while he asks for more attention to the ovaries. It is not a little interesting to general practitioners to remember in this connexion that an eminent English gynæcologist only last week in our columns spoke with refreshing positiveness of the dependence of severe hysteria on flexions of the uterus. Dr. Graily Hewitt said, "My own observation has led me to the conclusion that marked flexion of the uterus exists in all cases of severe repeated hysterical attacks." These attacks might be thought to have an ovarian rather than a uterine seat, if indeed it has any special seat in the sexual system. The probability is that either ovarian or uterine irritation, or any other irritation or shock, acting on the nervous centres of patients with a certain morbidness or irritability of the nervous constitution, suffices to set up hysterical phenomena. But we are digressing.

Dr. Duncan goes into the question of the connexion between sexual activity and the integrity of the ovaries, and recognises the dethronement of the ovaries from the supreme position in all departments of sexual activity. The persistence of sexual feelings after the complete removal of the ovaries is the principal fact quoted by him, inclining him to believe that the sexual function has its head-quarters in a certain portion of the lumbar spine, rather than in the ovaries. Still, Dr. Duncan is of opinion that the dethronement of the ovaries is not yet complete, and that there is still much truth in the ordinary views of practitioners as to their being the *fons et origo* of all the sexual functions. All practitioners are not of this opinion, and our readers will remember the letter in which, last year, Mr. William Henry Kesteven claimed for his father priority in contesting the commonly accepted view of the ovular theory of menstruation. Dr. Duncan discusses the question of ovariotomy; the subject of ovaritis, acute and chronic; hæmatocele; the present state of our knowledge of the anatomy and physiology of the ovary. Careful bimanual examination is lauded as the chief means of physical diagnosis, especially for the detection of ovaritis, uncomplicated with adhesions. He regards our improved knowledge of ovaritis as one of the greatest steps of progress in modern gynæcology. His view of the importance of the diagnosis of it may be gathered from the following words:—

> "This diagnosis is a matter of very great moment to the practitioner, not only on its own account, for that is a matter of course, but also on account of the value of its discovery as a contraindication—to which Nélaton is said to have attached importance—of various other gynæcological operations. There are in few kinds of cases more frequent occasions for correction of treatment than those that occur under this category. How often is a pessary intolerable because an ovaritis has been neglected! How often is a uterine catarrh inveterate, or a displacement supposed to be painful, or a metritis supposed to be peculiar, when there is an explanation in the neglect of an ovaritis!"

SMALL-POX AND CERTIFICATES OF CAUSE OF DEATH.

The opposition to compulsory vaccination, as an infringement of the liberty of the subject, is one of the most depressing signs of a certain phase of so-called liberalism, which is unfortunately finding great favour just now among a large section of the working classes. The claim of Alderman Tatham at a recent anti-vaccination meeting in Leeds, that "every man should have the control of his own body and of the bodies of his children in a matter of this kind," is however, so illogical, and would be dangerous in so many ways to the progress of civilisation, that there is little chance of such a doctrine ultimately prevailing. Although statistics carry little weight with anti-vaccinators, this should not prevent a strong effort being made to render figures relating to small-pox and vaccination as complete as possible. At present they are lamentably incomplete and unsatisfactory. Except in hospitals, the medical certificates of the cause of death in nine out of ten omit, in fatal cases of small-pox, to state whether the deceased had been vaccinated or not. Dr. Goldie, in his annual report upon the sanitary condition of Leeds in 1874, states that 121 cases of small-pox were admitted into the Small-pox Hospital of that town during the year. No death occurred among 55 who had been efficiently vaccinated; there were 4 deaths among 30 imperfectly vaccinated; 9 among 24 unvaccinated; and 3 among 12 regarding whose vaccination there was no evidence. At the anti-vaccination meeting above referred to, Councillor Kenworthy declared his disbelief of all statistics relating to this question, and did not hesitate to say that he knew them to be "cooked." It is to be hoped, however, that medical practitioners in future will do their best to increase our knowledge on this important subject, by inserting on their certificates of the cause of death information as to the vaccination of persons who die of small-pox. The want of this co-operation on the part of the medical profession destroys the value of the statistics relating to small-pox published by the Registrar-General.

BLOOD-CORPUSCLES.

In a brief historical sketch of the mammalian red blood-corpuscles, Dr. Norris, of Birmingham, observes that these minute bodies were first seen in the year 1658 by Swammerdaux, though his observations were not published till a century later. In 1661 Malpighi published his discovery of the blood-corpuscles of the hedgehog. He erroneously regarded them as globules of fat. Leeuwenhoek, in 1673, detected them in human blood, and from this time the study of these bodies commenced in earnest. Hewson, in 1770, showed that in the normal state they were not globules, but flat bodies. Dr. Young, in 1813, inferred that they were biconcave discs, and this was demonstrated by Dr. Hodgkin and Mr. Liston in 1827. The researches of many observers, amongst whom Gulliver and Wharton Jones are conspicuous, have proved that the red corpuscles are destitute of a nucleus, that they have a diameter of about $\frac{1}{3200}$ of an inch, and a thickness of about $\frac{1}{12000}$ of an inch. The running together of the discs into rouleaux was first observed by Hewson, and first depicted by Della Torre about three years subsequently. In 1862 the nature of this phenomenon was investigated by Dr. Norris, who pointed out a form of aggregation of the corpuscles which had been overlooked by previous observers, and which he designated the tesselate mode of aggregation, and at the same time demonstrated experimentally that aggregation in both cases was dependent upon a peculiar operation of the force of cohesion. In regard to their physical constitution, whilst they were formerly regarded as vesicles, they are now considered to be tiny lumps of a uniformly viscous matter, with at most only a pellicular covering. Their mode of origin is obscure, but is generally attributed to transformation of the white corpuscle. Dr. Norris, however, holds that, like the formless elements of the blood, these morphological elements are produced *de novo* from the food and fluids of the body; and in support of his view states, as the result of his observations, that the colouring principles associated with plants and animals, such as hematin or cruorin, chlorophyll or carmine, possess the power, under suitable conditions, of combining with protein and other substances, and to produce instantaneously, by a process of precipitation, equable-sized organic globules, which are permanent in the surrounding aqueous fluids. These morphological elements are therefore the immediate result of the mere admixture of suitable formless fluids. Hence it would appear that if in any part of the economy hæmatin and globulin come together in the presence of a third suitable organic liquid, hæmoglobin corpuscles must inevitably be produced in numbers proportionate to the amount of hæmoglobin present. This Dr. Norris believes probably occurs in the lymphatic glands, but there is no reason why it should be exclusively confined to this region.

In accordance with this view Dr. Norris remarks we have no longer to search for transition forms (which have been looked for in vain), but only for the chemical substances, the organs which elaborate them, and the regions in which they combine. This view refers the formation of the blood as a whole almost entirely to the elements of the food.

THE CISTERNS IN LONDON HOUSES.

THE London season has now closed, and a walk through the deserted squares and streets will show how universal the exodus is that takes place at this period of the year. The large houses are no longer full of tenants, but are left in charge of one or two domestics, or professional "minders." A change on so large a scale must make an important impression on the sanitary condition of the city, for not only is less sewage poured into the drains, but also less water to flush them is used. It is difficult to say if the diminution in the quantity of sewage is proportionate to the diminished return of water to the sewers, but it would be an interesting point to ascertain. We wish now, however, to draw attention to the condition of the cisterns in empty houses during the dull months. These cisterns are generally constructed to contain sufficient water to meet the requirements of the house when full, allowing so many gallons per head for the estimated number of residents. During the season the cisterns can barely meet the demands made upon them, and consequently the water is thoroughly changed every day, or at the most every two days. When the family is from home the cisterns are seldom emptied, a small quantity only is withdrawn every day, generally from one cistern—the most accessible—the others being left unused. Consequently in these the water becomes stale, and even in the favoured cistern the quantity of fresh water admitted daily is too small, in proportion to the stale water left unused, to be either agreeable or wholesome. The family returns to town after many months' absence, and the water in these cisterns is, in many instances, used by them when it must be in a very bad condition from long storage. We would advise householders to give injunctions to their servants or those left in charge, to draw off the water in all cisterns in the house at least once a week during their absence, and before returning to have the cisterns themselves thoroughly cleaned out. By doing this they will ensure a wholesome and fresh supply of water for themselves, and the water poured into the house-drains in considerable quantities by these weekly flushings will keep them clean and sweet, and carry off any impurities or sewer-gas that may collect in them. They will also benefit their neighbours by returning to the main sewers a quantity of water for flushing at a time when it is much required.

MUIR v. RIDGWAY AND ANOTHER.

AMONGST the cases set down for trial in the Home Circuit during the present Assizes, was an action for libel, brought by Sir William Muir, the Director-General of the Army Medical Department, against Messrs. Ridgway, the proprietors of the *Broad Arrow*. The case came on before the Lord Chief Baron and a special jury at Croydon, on the 9th inst.

Mr. Hawkins, Q.C., who appeared for the plaintiff, said that Sir William Muir had been compelled to bring this action in consequence of some charges that were made against him, which he considered seriously reflected upon his character, in a newspaper called the *Broad Arrow*, of which the defendants were the proprietors. The defendants, however, had done what the managers of all the respectable journals were always ready to do when they discovered that a wrong had been done—had admitted that they were not justified in publishing the article in question, and that there was no foundation for the charges that had been made against the plaintiff. Sir William Muir had no other object in view in bringing the action than to vindicate his character, and he was perfectly satisfied with the explanation of the defendants, and arrangements having been made for indemnifying Sir William Muir against all the expenses that he had been put to in the matter, he would consent to a juror being withdrawn.

Mr. Harrison, on behalf of the defendants, said that the letter complained of had been inserted by inadvertence, but it really did not contain, according to their view of it, any charges against the plaintiff. He, however, was ready to disclaim any intention on the part of his clients to make such charges against the plaintiff, and to withdraw any imputations that were supposed to be cast upon the plaintiff by the article in question.

A juror was then withdrawn, and the Lord Chief Baron, addressing the jury, said that this was a most satisfactory termination of the case. All imputations, if there were any in the paper, which had not been read to them, were withdrawn, and the very high character that Sir William Muir always has sustained will remain unimpeached by any doubt or imputation that may at all have been cast upon him by anything that has appeared in the publication.

THE BRITISH MEDICAL ASSOCIATION AND DIPSOMANIA.

THE Treatment of Habitual Drunkards formed the subject of two papers in the Public Medicine Section of the British Medical Association meeting in Edinburgh, on Thursday week. The point of Dr. Peddie's paper was the identity of the State relations of the suicide and of the dipsomaniac; and the essentially morbid mental condition of the latter, which justifies and needs restraint. Dr. G. F. Boddington, the author of the second paper "On the Control and Restraint of Habitual Drunkards," urged strongly the magnitude of the evil and the need for legislation. Mr. Playfair testified to the weight of the evidence, which was brought before the Parliamentary Committee, as to the efficacy of the proposed measure. A resolution was carried, on the motion of Prof. Christison and Dr. Husband of York, "That excessive intemperance is in many cases a symptom of a special form of insanity, which requires special treatment, with a view, first, to the recovery of those affected, and, secondly, to the protection and advantage of them and of society; that in the present state of the law such treatment is not attainable; and that it is desirable that legal provision should be made to render it attainable." At the general meeting of the Association on the following day, the motion was referred to the Committee on Habitual Drunkards appointed by the Council. Dr. Ritchie, of Edinburgh, however, suggested that the relationship to insanity, pointed out in the resolution, would mislead the general public, and moved a resolution which recognised more clearly the need for State control of all cases, "whether the result of vice or the manifestation of a special form of insanity." The resolution, however, met with no support, probably because the subject was merely to be referred to the Committee. Dr. Ritchie undoubtedly touched a point which will have to be most carefully considered in every resolution or authoritative suggestion which is put forward on the subject, if the present movement is to have any chance of success. While the essential relationship between insanity and dipsomania is carefully asserted as one of the most important grounds on which legislation is justified, the practical distinction between the two classes of cases must be maintained with the greatest care. Once let the idea get abroad among the public that "the doctors want to shut up all drunkards in lunatic asylums," and an opposition will be raised which will be fatal. We have no doubt that the Committee of Council will give every consideration to the point of Dr. Ritchie's proposed resolution, as it indeed deserves.

THE WATER-SUPPLY AT HASTINGS.

HASTINGS was one of the first of our watering-places to undertake the task of improving its drainage, by constructing a large main sewer, which carried the town drainage to a point a considerable distance to the eastward from the town. The completed scheme has not yet been in operation a sufficient time to make much impression on the death-rate, yet it is satisfactory to notice that the deaths from zymotic diseases have fallen considerably during the last four years, the rate for the four years ending 1874 being 1·8 per 1000, as compared with 3·0 for the decennial period ending 1870. Whilst congratulating the authorities on the improvement of the town drainage, and the advantages they may now expect to accrue from it, we must call their attention to the defective nature of the water-supply—defective certainly in quantity, and frequently, we fear, in quality. Complaints have reached us on both scores, and this spring it came under our own immediate notice. We think in many cases the impurity of the water was caused by the filthy condition of the cisterns in the lodging-houses. But, looking at the sources of the present water-supply, we also feel assured that, in dry seasons especially, the water may acquire considerable organic impurities before its distribution. The question of an increased water-supply has been before the sanitary authority for many months, and they have received many able reports on the subject. It is not our province to dictate which of the proposed schemes is the best, but it is our duty to urge the town authorities speedily to adopt some scheme which will not only secure for the town an ample and pure supply sufficient for its present requirements, but also to make provision for the increasing population. In any case the supply ought to be made constant. Independent of the dangers of the intermittent system, which have been frequently illustrated in our columns, an intermittent supply requires the use of house cisterns for domestic storage. In our own homes we can see that these are regularly cleaned out. In lodging-houses, however, the owners are often too busy or harassed to think of such particulars, even if they regard them as necessary, and we believe many of the complaints that so frequently arise at the different seaside resorts on the score of bad water are attributable to this cause. Visitors whose attention is drawn to any defect in the quality of the water supplied them should inquire into this point, and put themselves in communication with the medical officer of health of the town. If the impurity is due to a foul cistern, it can be easily remedied; if from an originally contaminated water-supply, such complaints will strengthen the medical officer's hands in his endeavours to secure for the town water of better quality. In all cases it should be remembered that a deficient water-supply calls for increased storage, and it is well known that many waters deteriorate and acquire organic impurities during the period they remain in reservoirs and cisterns.

THE TOXIC EFFECTS OF PUTREFIED BLOOD.

SOME very interesting observations on the toxic effects of putrefying blood have been recently communicated to the Académie des Sciences by M. V. Feltz. Their object was to ascertain how far the toxic property could be influenced by various conditions. He first determined the effects on a healthy dog. The injection of one to three cubic centimetres caused all the symptoms of intense septicæmia, pyrexia, vomiting, hæmorrhages, and death, in from three to eight days, with pulmonary infarctions and evidence of fatty degeneration in both blood and liver. Exposure to the air for periods of 24 to 96 hours made no difference in the toxic properties of the blood; exposure to compressed air for 24 to 144 hours likewise had no influence. The microscopic characters of the blood remained unchanged, but the vibrios it contained were a little less active. The toxic effects were the same. Exposure to oxygen had a different result, according to the time of exposure. Contact with oxygen for from 6 to 72 hours did not lessen the poisonous qualities; animals injected died as in the other cases. Those injected with blood which had been exposed to oxygen for 96 to 216 hours recovered after five or six days' illness. The exposure rendered the bacteria &c. inactive. The result was the same with blood through which a continuous current of oxygen was passed. A very similar effect was produced by exposure of the blood to a vacuum for many hours. Some animals which were injected recovered, others died, but the difference was less clearly related to the duration of the exposure. A second series of experiments was to determine the influence of time on the poisonous material. When the putrefied blood was kept so long that no living bodies could be discovered in it by microscopical examination, the same toxic effects were produced by its injection, but were less intense. Some animals recovered, and those which died lived a longer time—ten or twelve days. The post-mortem appearances were the same. Their blood, examined immediately after death, contained active bacteria, vibrios, &c. Putrefied blood was then dried by slow exposure to the air, powdered, mixed with distilled water, and injected. The effects were not, as in the other cases, immediately manifest. After four to six days of incubation, the animals became ill; two died on the tenth and sixteenth days, others recovered. The lesions were the same: the blood contained active bacteria and vibrios. M. Feltz concludes that, as exposure to a vacuum and desiccation did not remove the toxic agent, it cannot be a gas; that activity on the part of the minute moving particles within it is not necessary for its septic effect, and that the development of bacteria &c. in the blood of the animals injected points to the germs of those bacteria as being the probable efficient means of the production of the poisonous effects.

COMPLETION OF THE METROPOLITAN MAIN DRAINAGE.

A labour of sixteen years, and the expenditure of more than four millions sterling, has brought to a successful completion the gigantic undertaking known as the metropolitan main drainage system, which was commenced in 1859. The whole of the sewage of more than four millions of people, living on an area of over 117 square miles, is now diverted from the Thames near London, and discharged at Barking and Crossness, fourteen miles below London-bridge, into the river at high water, in order that the ebbing tide may carry it out to sea. Until the opening of the western pumping station at Pimlico on the 5th inst. the sewage of an area of nearly fifteen square miles of West London, including Chelsea, Fulham, Brompton, Kensington, Shepherd's-bush, Wormwood-scrubs, Notting-hill, and Hammersmith, was discharged into the Thames at Cremorne. The last portion of the metropolitan sewage has now been diverted from this part of the Thames, is lifted to a height of eighteen feet, and then finds its way into the low level sewer, which carries it to the Abbey Mills pumping-station. So recently as 1815 a penalty was incurred by discharging house drainage into the sewers, which were only intended for surface drainage. Up to that date the cesspool system reigned supreme in London. The nuisance of this system, however, became so intolerable that in 1847 a law was passed making cesspools illegal, and requiring all householders to do what was a penal offence before 1815—that is, to drain into the sewers. In the meantime, however, the Thames was rapidly becoming a gigantic open sewer, and three warnings in the shape of cholera epidemics in 1832, 1849, and 1854, combined with the powerful incentive to action in the matter produced by the effluvium of the Thames upon the legislators in the Houses of Parliament, led to the inauguration of the metropolitan main drainage system in 1859. The system is now complete, but the sixteen years during which it has been in progress have passed without the solution of the problem how to utilise this vast amount of sewage now cast into the sea. This still remains to be solved.

DISCOVERY OF THE MEDICINAL PROPERTIES OF NITRITE OF AMYL.

It was natural for Dr. Warburton Begbie, in his address delivered in Edinburgh, to give all the honour he could to the Medical School of that city. But he passed altogether the bounds of historical accuracy and contemporary justice when he gave to Dr. Lauder Brunton the credit of having, by original research, added the nitrite of amyl to the armoury of practical medicine. The first notice of the effects of the nitrite in producing breathlessness and flushing of the face was by Professor Guthrie; the first systematic, physiological, and therapeutical researches with the nitrite were by Dr. Benjamin W. Richardson. In his report on Nitrite of Amyl made to the British Association for the Advancement of Science at the Newcastle meeting in 1863, Dr. Richardson originally introduced nitrite of amyl into medicine, and in his next and very full report to the Association at the Bath meeting, and in following years he detailed and defined still more carefully, not only the physiological action of the nitrite, but its true position as a therapeutic agent. It was, he showed, as an antispasmodic and as the most potent known relaxant of vascular tension that it took its place in medicine. It would control even strychnine tetanus, and it was to the relief of acute spasmodic and tetanoid affections that it should be applied. Dr. Lauder Brunton, Dr. Haddon, the late Dr. Anstie, Mr. Foster of Huntingdon, and Dr. Farquharson, deserve every credit for being earliest in the field in taking advantage of the knowledge thus supplied, the first-named gentleman having employed the suggested remedy in angina pectoris, the second in cholera, the third in asthma, the fourth in traumatic tetanus, with success, and the fifth in a case of intestinal spasm. But previous to the observations of any of these gentlemen the action, the application, and even the mode of application of nitrite of amyl as a remedy were with much labour discovered, collected, and given to the medical and scientific world by Dr. Richardson.

GROUNDLESS CHARGE AGAINST A SURGEON.

It is bad enough to have a case of rupture of the uterus, which we are all liable to have, but it is a terrible addition to one's misfortunes to have the accident treated as a crime. This was the hard case of Mr. William John Haram Wood, of Boston, who was charged at the recent Lincoln Assizes with feloniously killing and slaying Mary Elizabeth Wright. The circumstances of the case will be remembered by our readers. Mrs. Wright had flooding, which necessitated delivery by turning, which she seemed to bear very well. Mr. Wood left shortly after delivery. Collapse set in, and the patient died in two or three hours, before Mr. Wood could be fetched. Before leaving he did not apply a binder, and he left no very specific instructions about the administration of stimulants. On his arrival after the death of the patient, Mr. Wood was surprised to hear of the event. A post-mortem examination revealed the existence of rupture of the uterus. On the strength of these facts the above serious charge was brought against Mr. Wood. The case for the prosecution broke down completely, so completely that, after hearing the evidence of Dr. Lowe, Mr. Bristowe, Q.C., the leading counsel for the prosecution, said that he was unable to proceed with the case further, as it was perfectly clear from the evidence of Dr. Lowe that the skill or care of no medical man could have saved the deceased. The judge fully concurred with the learned counsel. He advised the jury to return a verdict of "Not guilty." But he added it was very proper that the death of the deceased should have been inquired into, and he hoped the medical gentlemen attending such cases would wait a little longer after the delivery. The jury immediately returned a verdict of "Not guilty." The judge's advice as to waiting a little longer with cases in which anything unusual has occurred is very reasonable, but we cannot agree with the learned judge that there was any propriety in the trial. The result confirms us in the opinion we expressed in our first notice of the case, that the magistrates should have dismissed it. A medical man's grief at such occurrences is great enough without his life being embittered by unreasonable charges of neglect. Mr. Wood may, however, take to himself this consolation, that the case against him had to be abandoned by the prosecution.

DROWNING IN THE BATHING AND BOATING SEASON.

The Registrar-General, in his last Weekly Return, calls attention to the recent considerable increase of deaths from accidental drowning in the metropolis. During the fourteen days ending the 7th inst. it appears that twenty-nine deaths resulted from drowning, which exceeded by more than 25 per cent. the corrected average number from the same cause in the corresponding period of the last ten years. Each summer season there is an increase in the fatal cases of drowning. In 1874 they averaged 12 per week in London during the months of July and August, whereas in the other forty-four weeks of the year they did not average more than 5 per week. The description of the cause of death in the death register is often too indefinite for the purpose of deciding whether the drowning results from bathing, boating, or other cause. With regard to the fifteen deaths from drowning registered in London during the first seven days of this month, it may be stated that bathing was the assigned cause in only two cases, while in several the information furnished by the coroner for the death register is insufficient to decide the circumstances under which the drowning took place. It appears probable that some of the cases described as "found drowned" are suicides, but unless so described, these deaths are referred to accident. The fifteen deaths from drowning above mentioned included eight in the Thames, four in canals, and two in the Lea.

CEREBRAL HÆMORRHAGE WITH HEMI-ANÆSTHESIA.

THE occurrence of hemianæsthesia in lesions of the cerebral hemisphere has thrown much light upon the localisation of brain function. From the post-mortem researches of Türck, and the experiments undertaken by Veysierre, it has now been pretty well established that anæsthesia of one half of the body is most marked when the lesion invades the white matter just outside the optic thalamus, where the cerebral peduncle passes into the radiating crown of Reil—the part called by M. Charcot and others the "internal capsule"—and the neighbouring white substance of the posterior lobe. A case recently related by M. Raymond at the Société Anatomique fully bears this out. It concerned a woman eighty-nine years of age, who was under the care of M. Charcot at the Salpêtrière Hospital, who was attacked with apoplexy. There was profound coma, partial right hemiplegia, and complete right hemianæsthesia (no kind of stimulus applied to the skin leading to any response). On the left side both motor power and sensibility were perfectly retained. There was no appreciable difference in temperature between the two sides. Death occurred on the day after the seizure; and there was found a recent clot in the left hemisphere, taking a linear direction from the anterior extremity of the nucleus caudatus to about four centimetres from the posterior part of the occipital lobe. It involved the whole of the island of Reil, as well as part of the lenticular nucleus of the corpus striatum. The caudate nucleus and optic thalamus were free. M. Charcot remarked on the riband-like form taken by the clot, as being determined by the direction of the bundles of nerve-fibres between the lenticular nucleus and the "external capsule."

PRIVILEGED PEST-CENTRES.

IN their new-born anxiety to clear away the centres and foci of epidemic disease, we trust the authorities will not allow their attention to be diverted from those privileged hotbeds and nurseries of contagious and infectious maladies that exist in the closest proximity to some of our best and otherwise healthy residential property. It is a curious circumstance that nearly all the most salubrious localities in great cities, and particularly in the metropolis, are polluted by the presence of some wretched nest of filth and morbific poison, which enjoys the protection and thrives under the fostering care of the neighbourhood on which it preys. In some cases the plague-spot is a row of miserable hovels owned by some enterprising landlord, who lets out his tenements and allows them to be sublet in a fashion and under conditions fatal to public safety. It would not be difficult to point out instances of the nature to which we allude so flagrant as to constitute a scandal, and still wondrously overlooked. Another variety of the evil is yet more surprising in its character. Besides pest-centres maintained for love of lucre by unscrupulous proprietors, there are preserves which owe their toleration to the fact that they form the "sphere" of philanthropic enterprise. Just as Lazarus might have been patronised as an improving set-off to the grandeur, and an appropriate "object" for the benevolence of Dives, so these clusters of pestilent houses, these miserable courts, are kept by the undiscriminating charity of kindly people, who regard them as pet objects of liberality and practical goodness. It may seem a startling assertion, but it is nevertheless true, that such places exist, and have existed under the conditions we indicate, for a considerable length of time, in spite of the most earnest endeavours to get rid of them. No sooner is the deplorable character of one of these kept rookeries exposed than up starts the official representative of some philanthropic society or mission with a remonstrance pointing out how much matters have been mended within so many years, and a detailed laudation of the "good work" going on in the district which it is proposed to demolish. If our great cities are to be thoroughly cleansed, and *all* the causes and centres of disease are to be removed, public spirit will need to enter the lists against this mawkish philanthropy, just as in putting down mendicancy it is necessary to oppose almsgiving. It is not desirable, perhaps, to specify instances of the abuse we condemn; local authorities will have no difficulty in discovering them for themselves. But it is urgently requisite that such cases should be sought out while the new impulse of improvement is at its height, and we call attention to the risk of overlooking them in the hope that the evil may be rectified.

OUR SILENT HIGHWAY.

THE insanitary condition of the Thames from Richmond to Gravesend continues to be frequently pointed out. It would not be difficult to enumerate *seriatim* the nuisances that exist on the river and the surrounding banks. As to Richmond and other places above the main-drainage system that still discharge their sewage into the stream, the Conservators are responsible for compelling the authorities to divert such nuisances. As to foul cargoes, the sanitary authority is responsible, and has within the last week issued two official notices on the subject. As to factories along the river-side, it is believed that (chiefly owing to the exertions of the South-eastern and other Sanitary Associations), certain clauses have been introduced into the Public Health Bill which will enable local authorities to deal with these objectionable establishments. And as to the metropolitan main-drainage outfalls at Barking and Crossness, the Board of Works is responsible, and before long a great fight will occur between that Board and the Conservancy, resulting, as we prophesy, either in the utilisation of the sewage or the extension of the outfalls on both sides of the river. The Conservancy and the sanitary authority have always worked harmoniously, and much of the good already done by the latter has been owing to the able assistance received from the former.

THE HISTORY OF THE PLAGUE.

AN important note has been communicated to the French Académie des Sciences on the Chronology and Geography of the Plague in the Caucasus, Armenia, and Anatolia during the first half of the nineteenth century, by M. J. D. Tholozan, physician to the Shah of Persia. The information has been obtained from official records preserved in Trebizonde and Tiflis, &c. It appears that in the beginning of this century the plague lasted in the Caucasian provinces for more than eighteen years. It made its first appearance in the capital, almost in the centre of the country, and thence spread in all directions. Its most rapid and persistent movement was towards the north, whence the centre of Russia was seriously threatened in 1806—1816. About the Caspian its extension was slower and its stay briefer. To the south it made no movement, but it passed to the west into Turkey on several occasions. The account of the disease in Armenia and Anatolia presents a series of attacks in rapid succession, the longest period of immunity, for instance, at Trebizonde, being the sixteen years between 1814 and 1830. M. Tholozan's researches fill up a blank which previously existed in the history of the disease.

TABETIC ARTHRITIS.

M. CHARCOT has, more than once, called the attention of the profession to the joint lesions which occur in locomotor ataxy, and in showing recently to the Société de Biologie a collection of bones presenting these changes, he gave a summary of their special characters. These are clinical as well as anatomical. The affection appears commonly during the period of "lightning pains" before the inco-ordination of movement. First, there is grating in the joint; then a collection of liquid in it, with hard œdema of the limb; after a time the joint undergoes a species of dislocation. It is always chronic, is not usually attended with pain, and does not shorten life. The anatomical character is a progressive disappearance of the articular extremities without any bony prominences. The bones appear as if they had been ground down. The affection would seem to be less rare than is commonly supposed, since M. Charcot has seen fifty cases.

CHARITY VOTING REFORM.

THE last Report of the Charity Voting Reform Association, dated August 1st, shows, as regards the Royal Medical Benevolent College, that of 2357 subscribers who have recorded an opinion on the subject of voting, 2098 are in favour of its abolition, and 259 desire to retain the present condition of things; so that there is a majority of eight to one in favour of the memorial sent to the Council of the College some weeks ago, and to which we have already referred. Under these circumstances, it appears to be the bounden duty of the governing body of the Medical Benevolent College to discharge their responsibilities in this matter without delay, and, acting upon the expressed wishes of a large majority of the subscribers, to set a conspicuous example in the cause of charity voting reform.

H.M.S. *Shearwater* has just returned to the Medway from the East Coast of Africa, having been out on a surveying expedition in all parts of the world since July, 1871, when she was commanded by Captain Nares, the officer now commanding the Arctic expedition. We are informed that when off the coast of Zanzibar in the spring of the current year, a large proportion of the officers and crew were attacked with some form of remittent fever. We may anticipate some early particulars of these cases through the Medical Director-General of the Navy. Medical and sanitary particulars should be recorded minutely and published speedily for the benefit of those studying, and interested in, the etiology of disease as it occurs afloat.

AN outbreak of puerperal fever has occurred in the lying-in ward of the Caistor Workhouse. The guardians appear to be aware of the gravity of such an event, and have issued orders forbidding the admission of pregnant women to the institution until further notice. At first blame was thrown on the medical officer at the workhouse, but he has since been completely exonerated by the Local Government Board.

WHEN the epidemic of measles which has scourged Fiji first appeared, considerable blame was attached, even in official quarters, to the medical officer of the *Dido* for his laxity in permitting the King and his suite to land on the island without giving the population any sort of warning. In due time the ship-surgeon was requested to give an explanation of his conduct, when he appears to have completely cleared himself of a charge which, if proven, would certainly betray culpable carelessness in one occupying a responsible position. He apprised the Colonial Secretary and other officials that the men on board were suffering from measles, and pointed out the danger of communicating the disease, should they be landed. As the report of the inquiry into the affair ordered by the Admiralty must soon reach this country, it is better to reserve any further observations until then.

THE death of Mr. John Churchill is an event that deserves more than a brief notice. He may be said to have been the first great medical publisher in this country. During a long life, marked alike by enterprise and integrity, Mr. Churchill won the esteem of a numerous and influential section of the profession. For some years, while in business in Princes-street, Leicester-square, he published THE LANCET. Last week we incorrectly stated his age to have been seventy-three. He was a year older than this. Mr. Churchill's benevolence was well known, and he has bequeathed, in addition to other legacies of varying amounts, £500 to the Royal Medical Benevolent College, Epsom, and a similar sum to the Medical Benevolent Fund.

A PARLIAMENTARY PAPER has just been issued which gives, *in extenso*, a report furnished to the Home Secretary with reference to the conduct of Dr. F. R. Bernard, assistant-surgeon at Portland Convict Prison. A deceased convict named Larmont had made various charges of neglect against Dr. Bernard, but the Commissioners appointed to inquire into the case (Mr. W. J. Stopford, Director, and Dr. Briscoe, Inspector, of Convict Prisons, and Dr. Guy) came to the unanimous conclusion that Dr. Bernard "was not wanting in skill, attention, or substantial kindness to the deceased, or to the sick prisoners generally," but that in the performance of his duties he displayed a want of tact and temper.

THE Duke of Northumberland has given notice for next session of a motion for an address to the Queen praying for the appointment of a Royal Commission "to inquire into the working and management of works and manufactories smelting, burning, or converting ores and minerals, by which sulphurous acid, sulphuretted hydrogen, and ammoniacal or other gases are given off; to ascertain the effects produced thereby on the health of animal and vegetable life; and to report upon the best means to be adopted for the prevention of injury thereto arising from the exhalation of such acids and gases, and upon the legislative measures, if any, required for this purpose."

IN the House of Commons on Wednesday evening, Dr. O'Leary complained that the Public Health (Ireland) Act had proved inoperative, and he called upon the Government to take steps to have it amended. The Solicitor-General for Ireland, in reply, stated that the Act (which had been in operation only two months), as far as he was aware, was working exceedingly well, and was doing a vast amount of good. He thought it was too soon to form any definite opinion on the subject generally. Mr. Ward then said the remuneration paid to medical men was totally inadequate to the duties they performed, and would prevent the Act from being effectually carried out.

Dr. George Bland, in his second annual report of the sanitary condition of Macclesfield, has to point out many evils requiring vigorous action on the part of the health authorities. There are in the town 5199 houses which are unprovided with a proper system of drainage, the sewage from which is often allowed to flow on the surface of the ground. The out-door closets are, as a rule, defective in construction and insufficient in number. There appears to have been a considerable waste of infant life in Macclesfield during the year 1874. Among enthetic diseases we observe that five deaths are registered under the head of syphilis.

Recent letters from Syria state that cholera is now fearfully prevalent in Damascus, the mortality being very great. As many as 400 fresh cases a day have been reported. Sudden deaths frequently occur in the streets. There are no medical men, no medicines, and no bedding or clothing. Numerous cases of the disease are also recorded in Antioch. The district schools under British supervision have been closed, and the children dispersed. No special sanitary measures seem to have been adopted, the lethargic authorities contenting themselves with burning the clothes and effects of deceased persons.

One of the oldest medical officers of the army, Mr. Henry Franklin, C.B., Inspector-General of Hospitals, died on the 2nd inst. at Folkestone, in his eighty-ninth year. He entered the service as hospital assistant in August, 1808, and served in the Peninsula, in the American war, and in India from April, 1842, to June, 1850, and was present at the battles of Chilianwallah and Goojerat.

The Islington Vestry, after having pushed their opposition to the utmost, at their last meeting consented to pay the registrars for their valuable weekly returns, thus putting them in the same position as the country registrars have occupied, by Act of Parliament, for some years. The advocacy of our correspondent, Mr. Butterfield, has at last received its due reward.

Dr. Chas. Henry Leet, who from the commencement of the Medical Act has represented Apothecaries' Hall, Dublin, on the Medical Council, has just been re-elected to serve for the period of twelve months.

Dr. Wm. Stephenson, F.R.C.S. Edinburgh, has been appointed to the chair of Midwifery and Diseases of Women and Children in the University of Aberdeen, vacant by the death of Dr. Inglis.

The *Times of India* reports that Dr. Shortt has just successfully treated, by means of liquor potassæ and brandy, two persons who were bitten by cobras at Madras.

THE COLLEGE OF SURGEONS.

At the meeting of the Council on Monday, after the ordinary proceedings, the President referred to the Enabling Act, copies of which had been distributed to the members; and the thanks of the Council were given to Lord Selborne, Sir John Lubbock, and Dr. Lush, for carrying the Bill through the Houses of Parliament.

The President and Vice-Presidents were then requested "to take such steps as they may think proper for renewing negotiations with the other English medical authorities with a view to the formation of a Conjoint Examining Board for England, and report thereon to the Council." The question was raised as to the position of the last proposed scheme. Some of the members of the Council alleged that it was virtually defunct; others took an opposite view; but the general feeling was that there is very little, if any, vitality remaining in the scheme.

Letters were received from Mr. Hancock, Mr. Le Gros Clark, and Mr. Savory, resigning their seats as examiners. Mr. Hancock does not, we believe, seek re-election, but the President said that he had reason to think that the services of Mr. Clark and Mr. Savory on the Board would be retained.

The Council adjourned until October 13th and 14th; on the first of these days for the election of examiners, and the last for ordinary proceedings.

Mr. Hancock's motion, of which he gave notice at the former meeting, was not brought forward.

THE ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION.

The business of Friday, the 6th inst., and the fourth day of the meeting of the Association, was commenced at ten o'clock by the delivery of the Address in Physiology by Professor Rutherford, in the lecture-hall of the Museum of Science and Art. The address, an abstract of which we publish, was listened to with great attention by a large audience for about an hour. But as eleven o'clock approached many began to leave the hall in order to be present at the demonstration by Professor Lister in the Physiological Class-room in the university, of his method of investigation into the nature of putrefaction and other fermentative changes. Although the room was nearly filled at eleven o'clock, and crammed by a quarter-past eleven, Mr. Lister did not commence his demonstration till nearly half-past. The gist of his discourse was that putrefaction and fermentative changes were due to the presence of living organisms, and not to chemical processes. Mr. Lister maintained that if the dust and septic matter floating in ordinary air be excluded from putrescible fluids, such as milk or wine, no putrefaction or fermentative changes would occur, even though the purified air were freely admitted. In support of this allegation several appeals were made to actual experiments, which, as far as they went, seemed to confirm Mr. Lister's views.

If any evolutionists were present at this demonstration, they must indeed have been sceptical if they did not at once embrace the germ theory expounded by Mr. Lister. Even if the experiments were not convincing, the filthy condition of the atmosphere in the room ought to have removed any lingering doubt. It is no exaggeration to say that after between three and four hundred persons had been crammed into this ill-ventilated room for above two hours, the air positively stank. Most of those present must have been wellnigh poisoned.

So long did Mr. Lister continue his demonstration that there was not time left for the transaction of the other business in the Physiology Section, and several persons who had come to read papers went away evidently disappointed.

At half-past one in the afternoon the last, or, to speak more correctly, the complimentary general meeting was held in the Chemistry Class-room. The Report on Parliamentary Bills was handed in by Dr. Falconer, of Bath, and a resolution to the effect that the Association desired to afford effectual assistance in aid of the views expressed in the Public Health section regarding habitual drunkards was moved by Dr. A. P. Stewart, of London. A resolution was then read respecting the Scotch Poor-law medical relief; and a committee was appointed to inquire into and report upon the various anæsthetic agents used in surgical practice. Then came the usual votes of thanks, which we need not particularise here, and the proceedings terminated.

In the afternoon of the same day upwards of 3000 ladies and gentlemen attended a garden party in the Royal Botanic Gardens, given by Sir Alexander Grant and the Senatus Academicus of the University. Although the weather had been unfavourable during the earlier part of the day, it cleared up and the sun shone forth just before the hour of reception. The company on their arrival were received by Sir Alexander Grant and Lady Grant, and Professor Balfour and Mrs. Balfour. No efforts had been spared to render the gardens, hothouses, and museum but especially the latter, attractive and instructive. The excellent band of the Dragoon Guards performed upon the beautiful lawn between the rock garden and the herbarium, and the pipers of the Edinburgh Rifle Volunteers piped at intervals while marching on the gravel walk surrounding the house.

The meeting formally concluded on Saturday, when a large number of those who had been for three or four days attending meetings and listening to addresses and the reading of papers in close and crowded rooms, took advantage of one or other of the excursions to breathe again pure air. Some took steamboat to Bass Rock, some went to Melrose and Abbotsford, some to Hawthornden and Rosslyn, some to the Trossachs, while some were conducted by Mr. Cook through the beautiful districts in the west of Scotland, on their way to Staffa and Iona.

THE HEALTH OF SHEFFIELD IN 1874.

There is a considerable monotony about health report literature which is perhaps scarcely avoidable. Indeed, in some respects a still closer uniformity, especially in the tables of these reports, would add greatly to their value. It is, however, satisfactory to find a medical officer of health's report in which the figures are treated in a manner which is at the same time novel and valuable in throwing light upon some of the more important and least investigated branches of mortality statistics. Dr. Griffiths' report on the sanitary condition of the borough of Sheffield during the year 1874 is one which we can cordially commend to the notice, not only of medical officers of health, but also of all those who are interested in the important subject of the waste of life in our large towns. It is impossible in a short notice of this report to do more than refer to one or two of the many aspects under which the sanitary condition of Sheffield in 1874 is considered by Dr. Griffiths. The rate of increase of population in Sheffield during the decade 1861–70 was a high one, and assuming that this rate has been maintained since 1871, the number of inhabitants in the middle of the year 1874 was estimated by the Registrar-General at 261,029. The estimated increase of population in the borough during the year 1874 was 6764. The excess of births over deaths was, however, but 3849, and it follows that nearly 3000 persons must have been added to the population of the borough during the year by the balance of immigration over emigration. The area of the borough is so large that the population in 1874 did not average more than 13 persons to an acre; this, however, affords no clue to the real density of the population in the town itself. The birth-rate was equal to 42, and the death-rate to 27 per 1000 during 1874; each of these rates considerably exceeded the average for the year in the eighteen large towns. Dr. Griffiths does not attempt to account for the high death-rate by the high birth-rate, but has taken advantage of recent discussions on the subject to point out that the age distribution of the population in the borough is such that, sanitary conditions being equal, would produce, at the English Life-table rates, a mortality of 21·6 per 1000, or 2·9 below the rate in a stationary or life-table population, and 1·1 per 1000 lower than in a population the age distribution of which corresponds with that of England and Wales in 1871. The English Life-table is used in this report for calculating a standard death-rate for Sheffield, by which to measure the actual recorded death-rate at all ages, and at five groups of ages, and for each of the sexes. The value of this for tracing the source of the excessive mortality in towns is undoubted, and Dr. Griffiths has turned it to good account in dealing with the death-rate in Sheffield. The death-rate among males in Sheffield during 1874 exceeded the standard rate by 31 per cent., whereas the excess in the female rate was only 20 per cent. Between forty-five and sixty-five years of age the excess in the male death-rate was 37 per cent., whereas among women it did not exceed 12 per cent. The deleterious effects of town residence evidently operate more powerfully among men than women. This fact opens up an interesting subject for investigation and discussion. The death-rate in Sheffield shows the same depression between the ages of fifteen and thirty-five which is incidental to nearly all town populations, and it has recently been the subject of a paper read before the Statistical Society of London. The tables contain much valuable information as to the rates of mortality from different causes, not only in each of the five groups of ages, but in each of the nine registration subdistricts of the borough. Space forbids us to allude to the use which has been made of these tables in the report. An interesting comparison is also drawn between the effect of the remarkably cold period in the latter part of 1874 upon the rate of mortality in Sheffield and London. This comparison is somewhat disturbed at the early ages by the fatality of scarlet fever in Sheffield; but in each group of ages over twenty years the excessive death-rate due to this severely cold weather was lower in Sheffield than in London.

The statistics of vaccination for Sheffield are far from satisfactory, as they appear to show that more than 2500 children under one year of age remained unvaccinated at the end of the year, after allowance for those infants who died previously to the usual age for vaccination. It is important that health officers should keep themselves informed as to the proportion of the population of their districts which is unvaccinated, and that they should, for that purpose, exert their influence to secure an improved form of vaccination statistics. English statistics of vaccination are very inferior to those published by the Registrar-General of Scotland.

Dr. Griffiths states that the cause of death was uncertified in 572, or more than 5 per cent. of the deaths registered in Sheffield during 1874. It is certain that in a considerable number of these 572 cases there was no medical attendance whatever, but it is more than probable that the deceased in a still larger proportion had been attended by unqualified medical attendants, which would account for the cause of death being returned as "not certified." Now that the names of the certifying medical attendants are entered in the Register, much useful service may be rendered by health officers in checking unqualified medical practice. Valuable information and suggestions are contained in the report upon the sanitary condition of canal barges, the dwellings of the working classes, slaughter-houses, &c., which we can only afford space to mention. The want of mortuaries and of hospital accommodation for infectious diseases is also urged. We have read few reports of health officers which for soundness of their statistics and the amount of practical information they contain are superior to Dr. Griffiths' report for 1874 on Sheffield.

Correspondence.

"Audi alteram partem."

CHLOROFORM OR ETHER.

To the Editor of The Lancet.

Sir,—The relative *ultimate* safety of chloroform and ether is a very important question, and one that I have not seen noticed by any of the correspondents of the several medical journals.

My attention was drawn to this point last March, by Mr. Jessop, of Leeds, who informed me that he had almost abandoned ether as an anæsthetic in consequence of having lost several patients from bronchitis about the fifth day after operation; the bronchitis being induced, he believed, by the irritant action of the ether.

That patients more frequently die on the table under chloroform than under ether inhalation appears unquestionable; but if it be proved that ether occasionally produces fatal bronchitis, it behoves us to attempt to discover the cases in which this condition is likely to follow. I have not seen any death that I could directly trace to ether, though my experience inclines me to the opinion that the after-effects of ether are more persistent than those of chloroform or methylene, relish for food often being absent for several days. Since April, 1870, I have administered anæsthetics to 1144 patients: methylene in about 150 cases, ether in some 50, and chloroform in the remainder. I have never lost a patient. One ether case was in great peril; and about one in fifty of the chloroform cases exhibited dangerous symptoms.

It is an extremely difficult, and, I believe, almost impossible, matter for one to give chloroform in an interesting operation without taking an occasional look at the operation, and I fear that dangerous symptoms in fatal cases are, as a rule, not observed sufficiently early for treatment to be of avail. On Thursday last I gave chloroform to a healthy country girl of fourteen for the removal of a fatty tumour beneath the extensor muscles of the forearm. She had inhaled half a drachm, and was commencing the next when her face became dusky, her pupils dilated, pulse feeble, respiration shallow. I gently lowered the head, drew the chin away from the sternum, turned her slowly over on to the left side, and pressed firmly with my hand beneath the heart, and in a very short time her face regained its natural colour and her circulation and respiration their normal action. I resumed chloroform, but in a few minutes the dangerous symptoms returned, and the same measures were successfully resorted to. Chloroform was again given, and the perilous condition returned, and this time the respiration completely stopped. The measures for resuscitation were again successful. The operation was now almost completed, and I had no further anxiety about my patient, but gave a few whiffs of ether whilst the sutures were applied.

I have notes of several similar cases which I have treated by the above simple and ready method. Facial pallor or duskiness is usually the earliest symptom of danger, and on observing this I gently lower the head. If a good effect is not immediate, or if the respiration is failing, I raise the chin, and turn the patient over on to the left side. Galvanism I have never employed, and unless an assistant is at hand to use it whilst the above measures are being carried out, I think the battery is best out of the operating theatre. I fear many lives have been sacrificed from the *few minutes or moments* which must elapse before this instrument can be applied.

I am, Sir, your obedient servant,

Leicester, August 7th, 1875. FRANK H. HODGES.

DR. O'NEILL AND MR. F. J. CLARKE.

To the Editor of THE LANCET.

SIR,—I hope you will grant me the privilege of repelling a charge brought against my private character by Mr. F. J. Clarke in your impression of the 7th instant. The writer of the letter, with a well-feigned show of injured innocence, and with a kind of special pleading, endeavours to show that I, a medical man, have no right to interfere with his practices simply because he owes me a three years' bill for medical attendance, the payment of which he is seeking to evade. Mr. Clarke, as might have been expected, is wroth with me for having procured the analysis of his so-called "blood mixture," and, of course, looks out for motives, which he imagines he has found in my medical bills. At the time of his writing to THE LANCET he was perfectly well aware of my expressed intention to proceed against him for the non-payment of my fees, and that all the necessary information was in the hands of my solicitor, to whom he had easy access. When the indebtedness to me was first incurred there was expressed thankfulness and promises to pay when in a position to do so. Next came forgetfulness, and finally denial. I am extremely sorry that I should have to rebut a personal attack of this kind in THE LANCET, but it gives me an opportunity of thanking the Editor of this journal for the kindness and courtesy accorded to me, and also to thank my many professional friends, many of whom are personally unknown to me, for their approbation and sympathy. I may say, in conclusion, that the motives attempted to be fastened on me had nothing to do with my procuring the analysis. Since the so-called Blood Mixture came into anything like notoriety, which is only during the last few years, I felt that something should be done, but my thoughts never assumed a definite shape until lately.

I am, Sir, your obedient servant,

Lincoln, Aug. 9th, 1875. WILLIAM O'NEILL, M.D.

THE COLLEGE OF PHYSICIANS AND THE CLINICAL STUDY OF INSANITY.

To the Editor of THE LANCET.

SIR,—With reference to the petition to the Colleges of the Lecturers on Insanity, I enclose, with his permission, a copy of a portion of a letter which I recently received from the Registrar of the London College of Physicians, for which I hope you will kindly make room, as the knowledge of the step the College of Physicians has taken may induce other examining bodies to follow suit.

I am, Sir, your faithful servant,
R. H. B. WICKHAM,
Hon. Secretary to the Lecturers on Insanity.
Borough Asylum, Coxlodge, Newcastle-upon-Tyne, Aug. 10th, 1875.

[COPY.]

On the 19th July the following resolution was adopted at the Royal College of Physicians of London:—"That the Registrar prepare and submit a regulation to the College, 'That students who wish to qualify for the examination for the membership or licence of the College may substitute, if they so desire, a three months' course of clinical instruction in the wards of a lunatic asylum for the same period of attendance in the medical wards of a general hospital.'"

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At the last meeting of the Council the following Member was admitted a Fellow of the College:—

Poppleton Joe, L.S.A., Bradford, Yorks; diploma of membership dated Oct. 1838.

UNIVERSITY OF LONDON.—The following is a list of the candidates who have passed the recent 1st M.B. examination:—

ENTIRE EXAMINATION.

FIRST DIVISION.—Fredk. Lucas Benham, John Topham Gadsby, George Courtenay Henderson, and Richard Shalders Miller, University College; James John Macwhirter Dunbar and Francis Goodchild, St. George's Hospital; Thomas Ernest Hayward, Richard Lyddon, and Walter Pye, St. Bartholomew's Hospital; John Francis Nicholson, St. Thomas's Hospital; Arthur Bancks Prowse, Liverpool School of Medicine and St. Mary's Hospital; Harold Gilbertson Taylor and Fredk. Willcocks, King's College.

SECOND DIVISION.—James Blamey, James Wm. Bond, Henry Septimus Bott, Judson Sykes Bury, Claude Clarke Claremont, William Gristock, James Hudson, Christian Bernard Hunter, Alfred James, Boyd Burnett Joll, David Lloyd, John Mortimer, William Rumney Nicholson, Arthur Quarry Silcock, and Charles John Watson, University College; Charles Henry Cattle, Leeds School; William Edward Collins, St. George's Hospital; Henry Davy, Peter Horrocks, Montagu Lubbock, Edm. Howard Paddison, and Leader Henry Stevenson, Guy's Hospital; John Gilliott Garbutt, M.A., St. Mary's Hospital: William Pope Mears, London Hospital; Arthur Robert Wyatt Sedgefield, King's College; Wm. Frederick Shain and Joseph Wiglesworth, Liverpool School; J. Raglan Thomas and Hubert Foveaux Weiss, St. Bartholomew's Hospital; Arthur Thos. Wilkinson, B.A., B.Sc., Owens College.

EXCLUDING PHYSIOLOGY.

FIRST DIVISION.—Howard Griffiths Lowe, Queen's College, Birmingham; Samuel Thomson Plumbe, St. Bartholomew's Hospital.

SECOND DIVISION.—Charles Edward Beevor and William Henry Blake, University College; Alfred Edgar Drysdale, University College and Liverpool Infirmary; Waldemar Joseph Roeckel, St. Bartholomew's Hospital; Herbert Urmson Smith, St. Thomas's Hospital.

PHYSIOLOGY ONLY.

FIRST DIVISION.—Francis Richardson Cross, King's College.

SECOND DIVISION.—Samuel Ferguson Bigger, Liverpool Royal Infirmary; Henry Laurence Champneys and Alfred Finch, Guy's Hospital; John Benjamin Hellier, Leeds School of Medicine; Thomas Bower Smith, University College.

ARMY MEDICAL SERVICE.—The following is a list of candidates who were successful at both the London and Netley examinations recently held, having passed through a course of instruction at the Army Medical School, Netley:

	Marks.		Marks.
Charlesworth, H.	4261	Mapleton, E. A.	3976
Dorman, J. C.	4100	Kelsall, E. W.	3560
Le Mottée, G. H.	4014	O'Sullivan, D.	3435
Chester, W. L.	4006	Sharpe, C. E.	2933

NAVAL MEDICAL SERVICE.—The following candidates were successful at both the London and Netley examinations, recently held, having passed through a course of instruction at the Army Medical School, Netley:—

	Marks.		Marks.
Marsh, H. E.	4077	Lynch, A. B.	3148
Strickland, H. G. T.	3796	Dudley, J.	2843
Patterson, A.	3608	Sherlock, J. J.	2420
Ronan, M.	3393	Bookey, D. B.	2381
McAdam, J. A.	3285		

Apothecaries' Hall. — The following gentlemen passed their examination in the Science and Practice of Medicine and received certificates to practise on Aug. 5th:—

Dudgeon, John Matthew, Dalbeattie, Kirkcudbrightshire.
Edwardes, Edward Joshua, Llansantffraid, Montgomeryshire.
Highton, Thomas, St. Thomas's Hospital.

The following gentlemen passed the Primary Professional Examination on the same day:—

M. H. L. Allen and Charles F. Goode, St. Mary's Hospital; Owen Bowen, J. L. Jaquet, Westminster Hospital; Edward D. Moorehouse, Owens College; Robt. R. Harper and L. W. L. Joseph, St. Thomas's Hospital; Arthur Bennett, London Hospital; William Johnstone, University College; Percy K. Cree and William Walker, Middlesex Hospital; Charles Stephens, Liverpool Medical School; Thomas H. Gillam and F. A. Hallsworth, St. Bartholomew's Hospital.

The Court of Examiners elected by the Master, Wardens, and Court of Assistants of the Society of Apothecaries for the ensuing year were duly sworn in on Aug. 5th—viz., Robt. Norton, M.D.; Thos. Peregrine, M.D.; George Corfe, M.D.; James Parratt, M.D.; Robert Hunter Semple, M.D.; Charles Taylor, M.D.; Thos. Rivington Wheeler, F.R.C.S.E.; John Randall, M.D.; John Sherwood Stocker, M.D.; John Charles Thorowgood, M.D.; Robert Fowler, M.D.; and William Bathurst Woodman, M.D. Secretary and Registrar, Richard Hopkins Robertson, M.D.

Dr. R. J. Banning and Dr. Benjamin Barkus have been placed on the Commission of the Peace for Gateshead-on-Tyne.

Vaccination Grants.—Mr. George J. Perry (not "Berry," as previously announced), of Melksham, has been awarded £12 2*s.* for efficient vaccination; also Dr. H. J. Buck, Newport, Essex, £9 7*s.* (third time).

It is reported that yellow fever has broken out in Florida. The Navy yard at Pensacola is to be closed in consequence of the outbreak, and all unacclimatised officers and men are to proceed north until the danger is over.

The Quarterly Court of the Governors of the Brompton Hospital for Consumption was held last week in the Board-room of the institution. It was stated that the vacancies in the list of assistant-physicians had been filled up by the election of Drs. Green and Bruce, while Mr. R. Rendle, F.R.C.S., had been appointed resident medical officer.

Bequests, &c., to Medical Charities.—Mrs. Eliza Fallon, of Cabra, Co. Tipperary, bequeathed £3000 each to the St. Vincent Hospital, the Mater Misericordiæ Hospital, and the Hospital for Incurables, all at Dublin. The Birmingham and Midland Counties Orthopædic Hospital has received £250 under the will of the Rev. C. Ingleby. The quarterly report of the Hospital for Consumption, Brompton, acknowledges the receipt of legacies of £250 under the will of Miss Julia Gasquet, and £200 under that of Miss Sarah Clements.

Medical Appointments.

Anderson, R. M'G., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Senior Medical Officer to the West Derby Union Workhouse, Walton, vice Hughes, resigned.

Bates, C. P., M.R.C.S.E., has been appointed Medical Officer of Health for the Ramsey Sub-district of the Huntingdon Rural Sanitary District.

Canton, A. T., L.D.S., has been appointed an Assistant Dental Surgeon to the National Dental Hospital.

Clark, L., L.D.S., has been appointed an Assistant Dental Surgeon to the National Dental Hospital.

Coles, O., L.D.S., has been appointed Dental Surgeon to the National Dental Hospital, vice Steele, resigned.

Copeman, E., M.D., F.R.C.P.L., F.R.C.S.E., has been appointed Medical Officer of Health for the St. Faith Rural Sanitary District: Fees; acreage 47,974; population 10,901.

Cottle, W., B.A., F.R.C.S.E., L.R.C.P.L., has been appointed Assistant-Surgeon to the Hospital for Diseases of the Skin, vice Tay, appointed Surgeon.

Crabb, J., M.B., C.M., has been appointed Resident Surgeon to the Royal Hospital for Sick Children, Edinburgh.

Davis, W., M.R.C.S.E., has been appointed a Medical Officer to the Railway Carriage Company, Oldbury.

Duke, D., M.R.C.S.E., has been appointed a Surgeon to the Royal South London Dispensary, vice Constable, resigned.

Evans, A. P., M.R.C.S.E., has been appointed a Medical Officer to the Railway Carriage Company, Oldbury.

Gange, F. A., M.D., M.R.C.S.E., has been appointed Medical Officer and Public Vaccinator for the No. 2 District of the Faversham Union, and Medical Officer of Health for the No. 2 Sub-district of the Faversham Rural Sanitary District, vice Spyers, deceased.

Godlee, R. J., M.B., C.M., M.R.C.S.E., has been appointed Demonstrator of Anatomy at the Charing-cross Hospital Medical School.

Jolly, R., M.D., F.R.C.S.Ed., has been appointed Co-professor of Anatomy at Queen's College, Birmingham.

Lattey, A., M.R.C.S.E., has been appointed Medical Officer and Public Vaccinator for the Southminster District of the Maldon Union, Essex, vice Wigg, resigned.

Maccall, T., M.B., C.M., L.M., has been appointed Medical Officer to the Stockton and Darlington Railway Company, Crook District, vice Armour, resigned.

Murray, W., M.B., M.R.C.S.E., has been appointed a Medical Officer to the Pembroke Dispensary and Infirmary, vice Reid, resigned.

Newton, L., M.R.C.S.E., has been appointed Medical Officer of Health for the Alconbury and Sawtry Sub-districts of the Huntingdon Rural Sanitary District: £40 and £34 per annum.

O'Callaghan, K. M., L.F.P. & S. Glas., L.M., has been appointed Medical Officer and Public Vaccinator for the Aldeburgh District of the Plomesgate Union, Suffolk, vice Robbins, resigned.

Oldman, J., M.R.C.S.E., has been appointed Medical Officer of Health for the Huntingdon Sub-district of the Huntingdon Rural Sanitary District: £34 per annum.

Pemberton, T., L.R.C.P.Ed., L.M., L.R.C.S.E., has been appointed a Medical Officer to the Railway Carriage Company, Oldbury.

Raye, J. J. A., L.K.Q.C.P.I., has been appointed Medical Officer to the Lincoln United Friendly Societies' Dispensary, vice Goodall, resigned.

Rigby, J. M., L.R.C.P.L., M.R.C.S.E., has been appointed Medical Officer to the Eckington Amalgamated Medical Aid Association.

Rogers, G. O., M.R.C.S.E., has been appointed Medical Officer and Public Vaccinator for No. 1 District of the Newport Pagnell Union, vice Hailey.

Rogers, H. C., M.R.C.S.E., has been appointed Medical Officer for No. 10 District and the Workhouse of the Newport Pagnell Union, vice Hailey.

Shann, Mr. F., has been appointed a Resident Clinical Assistant at the Hospital for Consumption and Diseases of the Chest, Brompton, vice Parry, whose appointment has expired.

Snell, G., L.R.C.P.Ed., M.R.C.S.E., L.S.A.L., has been appointed Resident Medical Officer to the Kensington Dispensary, vice F. C. P. Howes, M.D., resigned.

Spooner, F. H., M.R.C.S.E., L.R.C.P.L., has been appointed Resident Midwifery Assistant to St. Bartholomew's Hospital, vice Champneys, resigned.

Stocker, J., L.D.S., has been appointed an Assistant Dental Surgeon to the National Dental Hospital, vice Gingell, resigned.

Thomas, R. R. G., M.D., L R.C.P.Ed., M.R.C.S.E., L.M., has been appointed Medical Officer and Public Vaccinator for the Tiverton West District of the Tiverton Union, vice Reddrop, resigned.

White, C. E., L.D.S., has been appointed an Assistant Dental Surgeon to the National Dental Hospital.

Williams, N., B.A., M.R.C.S.E., has been appointed House-Surgeon to the Carnarvonshire and Anglesey Infirmary and Dispensary, Bangor, vice Davies, deceased.

Wilson, Mr. A., has been appointed Lecturer on Natural History in the Edinburgh Extra-mural Medical School.

Births, Marriages, and Deaths.

BIRTHS.

Brietzcke.—On the 26th ult., at Ryde, the wife of Henry Brietzcke, F.R.C.S.E., of a daughter.

Carleton.—On the 3rd inst., at Delvin, Co. Westmeath, the wife of Wm. Carleton, M.B., of a daughter.

Carver.—On the 31st ult., at Cambridge, the wife of E. Carver, F.R.C.S.E., of a daughter.

Madigan.—On the 1st inst., at Drumcollogher, Co. Limerick, the wife of J. F. Madigan, L.R.C.P.Ed., of a son.

Nason.—On the 7th inst., at Cambridge-terrace, Kingstown, the wife of J. W. W. Nason, M.D., of a daughter.

Ollerhead.—On the 9th inst., at Blenheim-terrace, Minehead, the wife of Thomas J. Ollerhead, L.R.C.P.Ed., L.R.C.S.Ed., of a daughter.

MARRIAGES.

Downes—Hill.—On the 29th ult., at St. Luke's Church, Paddington, Edmund Downes, late Lieutenant in the Royal Artillery, and Missionary of the C.M.S. in the Punjab, to Mary Boughton, only daughter of the late Wm. Hill, Esq., of Bishop Wearmouth, Durham.

Sims—Fuller.—On the 5th inst., at St. Thomas's, Portman-square, Francis Manley Sims, F.R.C.S., of Half-moon-street, Piccadilly, to Alice Belgrave, second daughter of the late Henry William Fuller, M.D., Senior Physician to St. George's Hospital.

Stocker—Goodman.—On the 4th inst., at St. Paul's, Camden-square, N.W., Alonzo Henry Stocker, M.D., of Peckham House, Peckham, S.E., to Ada Mary, of The Terrace, Camden-square, N.W., elder daughter of the late Thomas Goodman, Esq.

DEATHS.

Bell.—On the 9th of June, at Copiabo, Chili, Robt. Carlyle Bell, M.D., aged 59.

Byrne.—On the 11th of June, at York-street, Cheetham, Manchester, P. Byrne, L.K.Q.C.P.I., aged 36.

Hynes.—On the 16th ult., Denis J. Hynes, L.K.Q.C.P.I., of Kinvara, Co. Galway.

Kerr.—On the 5th inst. (accidentally drowned at Millport), Arthur David Kerr, M.B., C.M., of Aberdeen.

O'Connell.—On the 3rd inst., at Glasthule, Kingstown, John O'Connell, L.M., aged 82.

Smith.—On the 28th ult., at Colombo, Ceylon (from the effects of a fall from his horse), Geo. A. C. Vernon Smith, M.R.C.S.E., aged 25.

[N.B.—*A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*]

Notes, Short Comments, and Answers to Correspondents.

The Influence of the Use of Wind Instruments on Chest Affections.

Dr. Burq, a French physician, who some time ago noticed the immunity from cholera, in the epidemic of 1849, experienced by people working in copper, and who accordingly proposed that metal as a remedy in the disease, has published a little book in which he endeavours to controvert, by reference to his own observations and personal experience, the notion commonly entertained that the use of wind instruments is injurious to individuals characterised by pectoral weakness. Dr. Burq remarks:—"Many philanthropists, on seeing our young military musicians wield enormous wind instruments, have sorrowed over the few years the poor fellows would have to live. Well, they are mistaken. All the men whose business it is to try the wind instruments made at the various factories before sending them off for sale are, without exception, free from pulmonary affections. I have known many who on entering upon this calling were very delicate, and who, nevertheless, though their duty obliged them to blow for hours together, enjoyed perfect health after a certain time. I am myself an instance of this. My mother died of consumption, eight children of hers fell victims to the same disease, and only three of us survive—and we all three play wind instruments. The day is not far distant, perhaps, when physicians will have recourse to our dreaded art in order to conquer pulmonary diseases."

Mr. R. H. A. Hunter.—We regret we cannot assist our correspondent in the matter.

Two Unusual Cases in General Practice.

To the Editor of The Lancet.

Sir,—The following cases have come under my notice in the practice of my friend Dr. F. W. Elliott, for whom, and during whose temporary absence, I am acting.

Case 1.—B——, a coachman in the employ of a gentleman residing in this neighbourhood, was watering his horses in the stable on Sunday morning last, when, as he states, he became suddenly and completely insensible. Upon coming to, he found that he had bitten his tongue, and caused it to bleed somewhat freely. He complained of stiffness and pain in his right shoulder on raising it. On examination I discovered fracture of the acromion process of the right scapula, but no other injury. It must, in my opinion, have been caused by the direct sudden impact of a horse's heel in kicking out from behind, and that, moreover, the suddenness of the attack caused him to bite his tongue.

Case 2.—S. M——, a female patient, first consulted me on the 20th inst. for an abscess which involved and encircled the umbilicus, and from which there had for some time past issued a thin, unhealthy, purulent discharge. As she was greatly out of health, I directed ferruginous tonics combined with quinine to be taken, and ordered linseed poultices to be kept constantly applied to the umbilicus. She called on me on the 22nd and 24th inst., by which time she seemed to have improved in health. Yesterday morning she called again, and produced for my inspection two large, nearly white gall-stones, which had, just previous to her coming to see me on this occasion, been discharged from the abscess. From the almost complete absence of inflammation now, I should be inclined to the opinion that no more gall-stones were to come away at present, although it is possible that at some future period more might be discharged. She about three months ago suffered severe pain in the right side, attended with violent sickness. It appears to me that these gall-stones, somewhat larger than ordinary, had, in endeavouring to pass the duct into the intestine, become impacted; had set up inflammation, and perforation resulted; that adhesions had formed between the duct and the abdominal wall; and that thereby, by gravitation and the formation of a sinus, they had descended to the umbilicus, and been in this way discharged.

As these two cases are rather exceptional, and might be interesting to some of your readers, I beg to offer this as my excuse for troubling you.

Your obedient servant,
Edward C. Anderson, Caius Coll. Cambs.
Knight's Hill, Lower Norwood, July 27th, 1875.

Salus Populi, (Ryde.)—In Dr. Layet's "Hygiène des Professions et des Industries" (Paris, Baillière), the author, before writing his book, examined with a physician's eyes the *employés* in the various industrial establishments when at work. The first section describes all the ailments peculiar to each industry, and the sanitary conditions, particularly that of ventilation, which are violated. The second section treats of the professions and their insanitary conditions—a very interesting study. The book, not quite a sealed one even for non-professional readers, will enhance the popular appreciation of State medicine.

The communication of *Dr. Clapham*, "On Nitrite of Amyl in Sea-sickness," shall appear next week.

D. A.—We are not aware of the existence of any legal definition of the word.

Californian Poison Oak.

To the Editor of The Lancet.

Sir,—In reply to "F. E. T.," who wrote respecting the above in your journal of July 3rd, I may say that the tree referred to is the *Rhus venenata*, which is capable by contact with the human skin of producing an erysipelatous eruption, with febrile disturbance. A tincture of the plant, in *very minute* doses, is often of service in erysipelas. The best known antidote is the tincture of *Ledum palustrum*. Others of the rhus family, such as *Rhus toxicodendron* and *Rhus radicans*, are credited with producing poisonous symptoms; but *Rhus venenata* is the most poisonous of all.

Yours &c.,
August 11th, 1875. A Reader of The Lancet.

Scarlet Fever in Wandsworth.

The Committee of the Wandsworth Board of Works, in a report presented last week, stated that they had carefully considered the reports of the medical officers of health for Battersea on the subject of the prevalence of scarlet fever in the neighbourhoods of Battersea-rise and New Wandsworth, and also the letters from Mr. Page and the Local Government Board on the same subject, and with the view of providing, as far as practicable, an immediate remedy for a complaint which they had reason to believe had been partly caused by the escape of gases from the sewers into houses in the higher portion of the parish of Battersea, owing to the sewers in the lower parts of such parish having been filled by the late heavy rains, they had instructed the Battersea surveyor immediately to construct ventilating shafts at the heads of the sewers in the following twenty-two roads—viz., Bellevue, Benerley, Brussels, Brodrick, Oberstein, Park, Varden's, Chivalry, Shelgate, Mallinson, Salcott, Cairns, Abyssinia, Auckland, Middleton, Chatham, Althorp, Nottingham, Louvaine, and Cologne Roads, and St. John's-hill and Bolingbroke-groves, and also to construct ventilating shafts at an average distance of about 100 yards apart to the sewers along the same roads.

Mr. C. Jeaffreson, (Newcastle.)—The paper was received in due time. We will endeavour to comply with our correspondent's request.

Dr. Carr, (Blackheath.)—Thanks.

The New Fever Department of the Sussex County Hospital.

To the Editor of The Lancet.

Sir,—I hasten to assure my friend Dr. Kebbell that his letter to The Lancet did not give me the least offence; on the contrary, I was very much obliged to him for affording me an opportunity of placing the real facts of the case before yourself and your readers. Whilst he confined his remarks to the local press, my official position precluded me from noticing them through the same channel; but when he addressed The Lancet with the declared intention of inducing that journal to alter its published opinion, then I felt it incumbent upon me to answer his letter, and place my opinions on record, and submit my arguments to a tribunal so capable of understanding the real issues in question.

I am glad that Dr. Kebbell so far repudiates the unfair tactics of his party in earnestly disavowing that he had anything to do with the widely circulated rumour (indirectly so complimentary to me) of my having inspired The Lancet.

Although Dr. Kebbell did not in so many words accuse me of misrepresentation, his letter certainly implied it, inasmuch as *the representation* which gave rise to the whole discussion was made by me in my official capacity.

Dr. Kebbell appears to be *angry* at my making use of his name so freely. My apology must be the activity he displayed, together with other members of his party, in canvassing the sanitary authority, and his many letters on the subject, to which he proudly and confidently appended that name, all of which led me to suppose that he was put forward by his colleagues and supporters as the ablest exponent of their views. Those were my reasons for writing the reply which has so *surprised* (and I should say also rather astonished) my excellent and learned friend, who shows much discretion in not wishing to continue the discussion.

I remain, Sir, your obedient servant,
R. P. B. Taaffe, M.D. Lond.,
August 7th, 1875. Medical Officer of Health for Brighton.

Mr. Gibb, of Airdrie, complains that, after an interval of two or three days, on visiting one of his cases of fracture of the neck of the thigh, put up as usual with a long splint, he found not only the splint removed, but the patient too. What concerned him still more was to find that his credit in connexion with the diagnosis and treatment of the case had also considerably disappeared. Two medical neighbours had been called in, removed the splint, and pronounced the case not one of fracture of the thigh, but of dislocation of the hip. They advised the patient's removal to the Glasgow Infirmary. Here Mr. Gibb's diagnosis was tested by examining the patient under chloroform, and it was fully confirmed. We are not prepared to say that no circumstances could justify such treatment of a case of alleged fracture under the care of a medical neighbour, but they would be circumstances of a very rare character. Mr. Gibb in this case has his satisfaction, and is not likely to find his diagnosis questioned again by the same parties.

Dr. J. T. Walker.—The advertisement is a very notorious one. Information as to the advertiser is still a desideratum.

The Death under Chloroform at Quarry Bank.

To the Editor of The Lancet.

Sir,—I have this evening read Mr. Ker's account of the post-mortem examination of the body of Matilda Wyatt, and need only say that, although the condition of the heart's cavities indicated syncope, yet the bloody froth exuding from the mouth and nostrils, and the intense violet tint of the face, as well as the condition of the lungs, pointed towards death by suffocation. Mr. Bradley (who assisted at the autopsy) and Dr. Walker agreed with me in the interpretation of the facts of the case. The abscess of the lungs was anything but a small one, and the statement that the abdomen contained three pints of pus is perfectly Munchausen in character. In the hurry of cross-examination I overstated the amount, which was, in reality, not more than three ounces diffused about. It is quite incorrect to say that I ever withdrew my statement that she was a bad subject for the administration of chloroform. The salient points of the case were those so ably commented upon in The Lancet. I am, Sir, yours obediently,
Brierley Hill, August 11th, 1875. George Ashmead.

P.S.—I only received the order from the coroner about four p.m. to make the post-mortem. I told the policeman I could not fix the time to half an hour, but would be as near to half-past six as I possibly could.

The Cultivation of Æsthetics in Schools.

Mr. W. Jolly, one of Her Majesty's inspectors of schools, calls attention, in his general report this year, to an important matter in connexion with the training of children. There is, he says, a passive education of taste carried on by the surroundings of a child in school—by the arrangements of the room, the decorations, the bearing of the teacher; all of which have an insensible effect on the future life and tone of character of the pupil. Hence the importance of making schoolrooms sweet and tasteful places. Mr. Jolly remarks that beautiful works of art can now be obtained at small cost through the aid offered by the Science and Art Department, and expresses the hope that, by means of such ornamentation and by a general air of refinement, schoolrooms may be made centres of bright and wholesome influences which shall perceptibly contribute to the elevation and happiness of the people.

Lex's communication shall receive attention next week.

The Cutaneous Eruption which sometimes follows Vaccination.

To the Editor of THE LANCET.

SIR,—Among the objections which are urged by the less educated classes against vaccination, there is one which is more ominous than others, and has some show of reason in it. I refer to the occurrence of a cutaneous eruption which follows so soon after the operation as to be attributed in some way to its effects upon the system in young children. At first we might be disposed to regard these cases as coincidences, and attempt to discourage belief in such an idea. There is an explanation, however, which it is probable has already been offered, to account for such cases, without contradiction to the belief that there is some connexion between vaccination and the cutaneous disorder which follows it.

From the observation that such a local inflammation as is produced by the application of caustic potash or similar substance in the treatment of nævus may give rise to certain general cutaneous changes, we are induced to ask the question whether the cutaneous lymphatic system in children may become affected in consequence of local suppuration, and, if so, in what manner this is to be explained? There is no difference apparently between the common form of diffuse dermatitis in children, as it occurs upon the head, neck, face, and other parts, whether following vaccination or not. It would certainly appear, however, that local inflammatory action or irritation of the skin is very liable to give rise to those various degrees of general alteration in the cutaneous tissue which we attempt to distinguish as eczema, impetigo, &c., though practically we may regard them as depending on inflammatory processes of different degrees of activity. The knowledge of these facts is very probably made use of by those acquainted with them to diminish the objection which an erroneous view of them would induce in regard to vaccination. It is possible that some of your readers may not yet have directed their attention to them, and may apply them practically in other ways, as, for instance, in deciding upon the propriety of performing vaccination in certain constitutional conditions, besides that of explaining the real connexion between the cutaneous eruption and the operation of vaccination.

I am, Sir, faithfully yours,

July, 1875. R. J. LEE.

A.M. Edin.—Vol. I. of the "Allgemeine Zeitschrift für Epidemiologie," edited by Küchenmeister. Its publisher is Enke, Erlangen. Its contents embrace a theoretical and a practical section, and, as far as it has gone, typhus constitutes the chief subject. The origin, and, above all, the differentiating features of this disease are minutely and clearly given. Cholera, too, comes in for a good deal of the same exhaustive handling—see particularly the paragraphs devoted to "Water as a Conveyer of the Cholera-poison."

Mr. H. E. Trestrail.—We regret our correspondent's letter is not quite suitable for our pages.

A Country Surgeon must attach his name to his letter if inserted.

Malposition of Urethral Orifice in a Female.

To the Editor of THE LANCET.

SIR,—A case has recently presented itself in my practice, which I opine will be of some interest to the students of gynæcology. I can find no notice of similar malformation in any of the obstetric treatises at my command, and I can imagine that the state of the parts hereafter described would considerably *puzzle* a practitioner endeavouring to pass a catheter, especially during labour.

E. M——, the wife of an engine-driver, sent for me, complaining of great bearing-down pain "as if something were come down between her legs." She had been married several years, had twice miscarried, and but for some derangement of the digestive organs had enjoyed good health. I proposed a vaginal examination, as I expected to find prolapse of the womb. I found the uterus *in situ*; but on the upper part of the vagina, about an inch from and within its external orifice, I felt what appeared to be the rough, everted edge of an ulcer. Puzzled at what appeared to be an unusual position for an ulcer even of specific origin, I subsequently examined with the speculum, when I discovered that what I at first imagined was an ulcer was an opening into the urethra; but on trying to pass a catheter I found that there was no orifice to the urethra in the usual situation, and this was the only opening to the meatus urinarius. The patient has perfect power of retaining her urine, and was utterly unconscious of being the subject of a malformation. She expressed herself as suffering pain at the time of connexion.

For the reason stated above I think it is a case which should be placed on record, and I shall be glad to learn through your columns if any similar cases have been met with.—I remain, Sir, yours &c.,

Rugby, August, 1875. JOHN INGLEBY MACKENZIE, M.B. Cantab.

J. R. C., (Edinburgh.)—According to the Report of the Science and Art Department of the Committee of Council of Education, the total number of persons who received direct instruction as students, or by means of lectures, in connexion with the Department in 1874 was 411,228, being an increase, as compared with the number in the previous year, of 54,728, or about 15 per cent.

Dr. John Gill.—The matter shall receive attention.

Remuneration of Lecturers: A Strike.

THE Director of the Edinburgh Museum of Science and Art, in his annual report just issued, says:—"I regret to say that the lectures to artisans have had to be suspended during the current session, owing to the unwillingness of the lecturers to continue their valuable services with such inadequate remuneration. The sums received by the six lecturers in 1873-4 average £9 2*s.*, which broadly gives only £1 10*s.* a lecture. If this sum could be subsidised to such an extent as to give a fee of £3 the lecture, the difficulty would be removed, and an admirable source of valuable instruction would be kept open to an earnest class of students, who, although not very numerous, are sufficiently so, I believe, to render their continued scientific training as valuable to the nation at large as to themselves individually."

Mr. Rivideau.—The matter has not been forgotten.

Congenital Absence of Bladder.

To the Editor of THE LANCET.

SIR,—The following is a description of a case of congenital absence of the bladder, which came under my care in the wards of St. John's Hospital in this city.

The patient is a boy of seventeen years of age. His general development is normal. In the position of the mons veneris is a red, fungous-looking patch of mucous membrane, resembling the mass which protrudes into the vagina through a large vesico-vaginal fistula. This patch is a trifle larger than a Spanish silver dollar. Near its inferior margin are the openings of the ureters, through which the urine is constantly dribbling away. At its inferior border is a transverse sulcus, about half an inch deep, at the bottom of which is a papillary protuberance, resembling the veru montanum, and at its summit two capillary openings, which are probably the openings of the ejaculatory ducts. The penis extends forward from the bottom of this sulcus. The skin of the uppor surface of the penis and the superior wall of the urethra are wanting. The floor of the urethra, forming the dorsal covering of the penis, and partaking of the characteristics of both skin and mucous membrane, extends to the extremity of the glans, and ends in a longitudinal depression in the situation of the meatus. At this point is a small fossa, corresponding to one of the follicles often found near the meatus. The prepuce hangs as a dewlap from the frænum. The symphysis pubis is wanting, its place being supplied by a ligamentous band, stretching from a point corresponding with the pubic spine on either side, across the hiatus. This band may be regarded anatomically as the reunion of the triangular ligament with the investing periosteum of the anterior and posterior surfaces of the pubic bones. No trace of a prostate could be detected. On either side of the mucous patch above alluded to is a hairy pad, following the course of its respective inguinal canal. These pads represent the two halves of the mons veneris. The right testicle is of normal size; the left considerably larger.

A cavity to hold the urine could readily be made by inverting a flap from the abdominal wall; but the absence of a sphincter would make the receptacle useless. All attempt at operative procedure was therefore abandoned.

Respectfully yours,

GEORGE E. VOST,

Beirût, July 27th, 1875. Surgeon to St. John's Hospital, &c.

T. E. K., (Bromsgrove.)—One of the most intelligent treatises on Cholera, in which the main theories broached within the last twenty-five years are succinctly stated and criticised, is Dr. Schauenberg's (Würzburg, 1874). The author is a firm believer in the "influence of a specific cholera germ on the more or less predisposed surface of the alimentary canal."

The Indian Medical Service.

To the Editor of THE LANCET.

SIR,—I was much pleased to see the letter on the above service in your issue of the 15th May, and would wish to bear testimony to all that the writer has said.

There can be little doubt but that the circular dated May, 1873, of the India Office distinctly says that a surgeon under five years' service, and having passed the examination in Hindustani, known as the "lower standard," will receive pay whilst in medical charge of a native regiment at the rate of 450 r. a month. But how many surgeons are there who, having qualified in the language, yet receive no such pay? As an example of such cases, take the following:—A., with eighteen years' service, goes home on furlough; B., with twelve months' service, holds medical charge of the regiment, but is said only to be "officiating." A.'s regimental pay is 800 r. a month; his unattached pay, 677 r., and the difference (123 r.) between these sums is divided between A. and B.! B., instead of receiving 450 r. for charge of the regiment, actually only receives his unattached pay, 286 r. per mensem, and half the 123 r., or 347 r. per mensem altogether. You are liable to hold such appointments for the first four years of your service, unless you are fortunate enough to have some interest to help you on. No mention of "officiating" appointments is made in the India Office circular, and it detracts materially from the rate of pay laid down to find yourself drawing 100 r. less than you expected.

I imagine there are many surgeons who would have hesitated before they entered the service had they known of the existence of such appointments; for it is at the outset of a surgeon's career that a liberal rate of pay is especially acceptable. Such an arrangement naturally benefits the senior men, so no word of complaint is heard from them. We, juniors, will be very content if we can only rid the service of "officiating" appointments.

I am, Sir, yours obediently,

Oudh, June 22nd, 1875. A SUFFERER.

Payment of Medical Officers as Witnesses.

To the Editor of THE LANCET.

SIR,—A short time ago I attended at a certain Assizes to give professional evidence (only) in a criminal case, and had only been paid my travelling expenses. I have been told that, being a military officer, I am not entitled to fees for professional evidence in civil matters; and being deplorably ignorant of all matters connected with the law, I trust that you or some of your readers will enlighten me on the subject, and, if I am deprived of my just rights, inform me what steps I must take to recover the amount.

I remain, Sir, yours truly,

August, 1875. A. M. D.

Speculation Baited.

H. Fly Smith, M.B. Oxon., kindly sends us the circular of Fritz Sevin, inviting him to speculate in the next draw of the Imperial Austrian Guaranteed State Loan; in other words, to send a cheque of £5 for the chance of getting a prize of £20,000! Mr. Smith directs especial attention to the taking way in which the agent begins his circular, thus:—"Sir: A gentleman in your neighbourhood, a client of mine of long standing, has given me your name and address as a likely party to speculate on a small scale." It requires some strength of mind to resist offers so cleverly and, withal, personally presented.

Mr. W. McDonald, (Maryhill.)—We are sorry we cannot comply with our correspondent's request.

L.R.C.P. Edin.—The question is settled, and does not admit of discussion.

Unqualified Medical Practitioners.

To the Editor of The Lancet.

Sir,—Your correspondent in The Lancet of July 24th, writing on the above subject, says that registrars of deaths should be supplied with a list of the registered medical practitioners of their respective districts, and that this should devolve on the Medical Council. Now, Sir, I fear your correspondent takes a very generous view of the Council. I registered myself last year, for which I had to pay the sum of £5. On the receipt handed to me, I saw printed that I was entitled to a copy of the Medical Register for the ensuing year gratis. The ensuing year has come, and has more than half passed, but no copy have I received. Now, Sir, when I don't get what I have paid for, and am promised, it is scarcely to be expected that registrars of deaths would be supplied with the Medical Register.

In answering a question some little time ago, you said the registration fees went towards the expenses of the Medical Council. The Medical Council, I presume, is supposed to look after the interests of legally qualified practitioners. I question whether that duty is performed, considering the number of men who are allowed to practise without a qualification.

I am, Sir, your obedient servant,

July 26th, 1875. Cedric Hurford, M.D. & M.B.

Erratum.—In Dr. Carter's article on the "Physical Cause of Presystolic Murmurs," which appeared in our last impression, page 204, col. 1, line 19 from bottom, for "forcible opening," read "forcible emptying."

Communications not noticed in the current number will receive attention in our issue of the ensuing week.

Communications, Letters, &c., have been received from—Prof. Rutherford, Edinburgh; Dr. Graily Hewitt, Paris; Dr. Althaus, London; Mr. Wilson, London; Dr. Hime, Sheffield; Mr. Perry, Melksham; Mr. Fairweather; Mr. Wilson, Edinburgh; Dr. Kitchener, Derby; Dr. Struthers, Aberdeen; Dr. O'Neill, Lincoln; Dr. Carr, Blackheath; Mr. Whitney, London; Mr. Hockley, London; Mr. Butterfield, London; Mr. Humphrey, London; Dr. Cannell, Calcutta; Mr. Angus, Newcastle-on-Tyne; Dr. Faber, London; Mr. Hunter, London; Mr. Sherlock, London; Mr. Henry, Lewisham; Dr. Eustace Smith, London; Mr. Lawson Tait, Birmingham; Mr. Carter, Birmingham; Dr. Ker, Brierley Hill; Mr. M'Kenna, London; Mr. Mackenzie, Rugby; Mr. Wickham, Newcastle; Mr. Johnston, London; Dr. Shaw, Bristol; Dr. Finch, Fisherton; Mr. Almond, London; Messrs. Hunterian Lectures
ON
SYPHILIS,
AND ON
SOME LOCAL DISEASES AFFECTING PRINCIPALLY THE ORGANS OF GENERATION.

Delivered at the Royal College of Surgeons of England,

By HENRY LEE, F.R.C.S.,

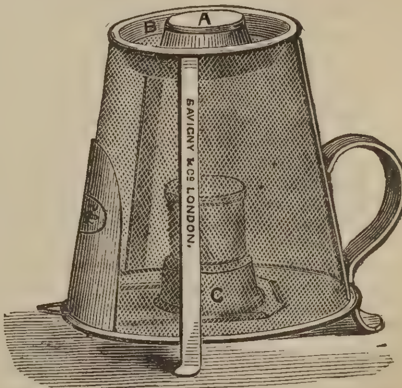
PROFESSOR OF SURGERY AND PATHOLOGY TO THE COLLEGE.

TREATMENT OF SYPHILIS.

Since Mr. Pearson and Sir B. Brodie's time another plan of administering mercury has been very extensively adopted here, on the continent, in India, and especially in America. Mr. Langston Parker's most valuable and energetic labours on the subject of mercurial fumigation suggested to me the ideas which I have endeavoured in some measure to work out; and as I find that the plan which I have advocated, although it has now come into very general use, is quite as imperfectly carried out in general practice as the administration of mercury in any other way, I am anxious to give a short but clear account of it. Abernethy long ago used calomel fumigation for the cure of syphilis, and, probably on account of the irritation which it produced when inhaled in excess, he appears to have abandoned its use. When calomel is volatilised, a certain amount of free hydrochloric acid is given off, as may be indicated by placing a piece of moist litmus paper in the fumes. In like manner the bisulphuret of mercury yields sulphurous acid, which is very much more irritating to the lungs. The so-called grey oxide of mercury often contains a proportion of calomel, and itself is liable to be decomposed in sublimation. Sometimes crude mercury is produced, sometimes the binoxide, so that its effects cannot be relied upon. These are the preparations of mercury which have been most extensively used for mercurial fumigation, and of these the calomel is much less liable to decomposition and produces much less irritation than the others. Experimentally, I found that the admixture of a small quantity of the vapour of water in a very great degree prevented the irritating effects of the sublimed calomel; and this is effected, as I suppose, by the admixture of the vapour of the water with the vapour of the hydrochloric acid. The irritating qualities of the vapour of calomel may be still further diminished by its being resublimed two or three times before it is used. In this action, as I conceive, any free hydrochloric acid is driven off. These seem very simple processes, but it is extraordinary the number of experiments that were tried, and the number of years that have elapsed since Abernethy's time, before they were practically applied. They have, however, converted that which was before an uncertain remedy, often attended with considerable inconvenience, into a mode of treatment at once safe and definite in its action, and one which may be regulated with the greatest nicety. Any remedy, as Sir B. Brodie has observed, that is powerful enough to do much good, may also do harm if misapplied; and I am anxious to guard against some of the sources of error which are very common at the present time in the use of the calomel vapour bath.

I would not for a moment have it inferred that I take for granted that the plan which I have advocated for mercurial fumigation will ultimately turn out to be the best possible. It is, however, but fair and reasonable that those who wish to try it should do so according to the plan recommended, before they pronounce an opinion as to its efficacy. In the first place, it is the calomel bath which I have recommended in the treatment of syphilis, and not a vapour bath. The water used is only for the purpose of softening and diluting any irritating vapour that may arise when the calomel is sublimed, and for this purpose half an ounce or an ounce is quite sufficient. I find that it is very common for a considerable quantity of water to be used; as this boils a certain amount of heat necessarily becomes latent, and as the vapour recondenses on the skin this latent heat is again given out. The result is often a profuse perspiration. A double evil results from this—the perspiration washes the calomel off the skin, where it should remain; and it, to a certain extent, debilitates the patient. Now many patients suffering from syphilis are already much reduced with regard to their physical powers, and will not bear any remedies of a depressing nature. A daily vapour bath becomes a tax upon the constitutions of such patients, which is a very serious addition to the causes of debility under which they already labour.

In the evidence before the commission to which I have referred, Mr. Cutler states that at St. George's Hospital he had tried the plan of treating syphilis by mercurial vapour baths, and found that patients were "knocked over" as soon by that mode of treatment as by the administration of mercury in other ways. It is not, however, stated what preparation of mercury was used. When I became surgeon to St. George's Hospital I took some pains to ascertain how the baths were given, and it was much the same in all cases. The patient was made to perspire profusely, and was afterwards rubbed dry. He was directed to put his head occasionally into the box in which he was placed, so as to breathe the fumes of the remedy. In the different institutions in London and elsewhere where medicated baths are given, this plan was, and is still, very generally adopted. With regard to it three points are to be noted:—1. The mercurial powder deposited on the skin, which, if it is to do any good at all, must there produce its effect, is immediately wiped off, and in so far its action is prevented. 2. The patient breathes the vapour in a concentrated form, and sometimes this produces inconvenient symptoms. 3. The perspiration not only weakens the patient, but itself is a means of removing the medicine from the surface of the skin. Each of these points is of importance, and applies to mercurial fumigations of all kinds. A patient in St. George's Hospital had a secondary syphilitic ulceration, which threatened to destroy one side of his nose. He was ordered a calomel vapour bath daily. He was thin and emaciated, and complained of increasing weakness during his treatment. I found that he was using a water vapour bath, as well as a calomel bath, and to this I attributed in some degree his increasing debility. He was directed to use his bath with very little water. A change for the better was immediately perceived, and the ulceration was very soon permanently healed. The fact of the debilitating effects of a daily steam bath I have now witnessed in a great number of instances, far too numerous to require any further particular illustration; and, in order that as few mistakes as possible may in future be made in this respect, I have had an apparatus constructed by Mr. Blaise which will hold an ounce of water only.



The inhalation of the vapour of mercurial preparations also requires attention. For want of this all the preparations which have at different times been used have in turn lost their reputation.

Dry mercurial preparations, as I have convinced myself by a number of experiments, irritate the lungs, and cannot be continued with impunity. In an institution in London with which I am not unacquainted, it was long the practice to give the mercurial baths in a room without a fire. The patient was undressed and covered by a Mackintosh cloak, and not unfrequently had a kind of shivering fit before he began his bath. The skin under such circumstances would certainly not be left in a good state for the action of the remedy.

I knew a case in which a patient was ordered a calomel bath for the whole body. The quantity to be used was half a drachm, and the ordinary calomel was used. By mistake he only inhaled the vapour, instead of having a bath for the whole body. A considerable degree of irritation of the lungs followed, with general disturbance of the constitution. I saw this patient at the expiration of four years, and he then, as I believe with more or less justice, attributed a chronic affection of his lungs to the mistake which had been made. It is true that the patient was of a strumous habit, and had before been treated with cod-liver oil, but it is equally true, in my opinion, that the irritation artificially produced tended to localise and develop his disease. In another case, in which a large quantity of the vapour of ordinary dry calomel was ordered to be inhaled, in the same thoughtless and mischievous way the patient's constitution was very much interfered with, and the skin of the face remained livid for some hours afterwards.

The third point which has been noticed—namely, that of wiping the mercurial powder off the skin immediately after it has been applied, is so much a matter of common sense, that in itself it requires no illustration. But, it may be asked, what proof is there that mercury is absorbed in this way? The answer to this is, that with regard to mercury, as with other medicines, we judge by the effects produced. There is probably no medicine which, when once taken into a patient's system, can be reproduced in the same state as that in which it was administered; there are few that can be reproduced in any state of combination. When mercury is given by the mouth or by inunction, it would be very difficult to prove its existence afterwards in the blood, but that it does affect the living actions of the blood we know by the results that are obtained. It is the same with regard to calomel applied to the surface of the skin, although its effects differ very materially in different individuals. A medical man of my acquaintance had brought his skin, by the constant use of baths of various kinds, into very fine condition. He found that he could never take a calomel bath two days together without the effects being visible on the gums. In trying this experiment he was as careful as possible not to inhale any of the vapour. There was nothing peculiar in this gentleman's constitution, as far as could be ascertained, with regard to mercury taken internally.

As an extreme example in the opposite direction, I may mention the case of a patient who came to me one morning, and said, "I have been going on as you directed." I replied that I was very sorry, but that I did not recollect him. "Oh! I don't wonder at that," he said, "it is two years and a half since I saw you." It turned out that he had been taking the calomel bath every night, sometimes for two and sometimes for three months at a time, and altogether he had taken about 900 baths. He was looking the picture of health, had nothing to complain of, and had long ago lost all the symptoms for which he originally came.

The plan which I have usually adopted then is as follows: A lamp, in which the methylated spirits of wine is burned, is put into a case, made principally of wire-gauze, on the principle of the Davy safety-lamp. The top of the case is fitted with a central, movable, small circular plate, surrounded by a trough, which should contain one ounce of water only. The water should be boiling when first put in, or should be allowed to remain over the lighted lamp until it begins to boil. Thirty grains of resublimed calomel are then spread out on the central small circular plate. This should be quite dry. The patient then sits, without his clothes, on a small stool or chair, and the lamp is placed between his legs. A cloak made of moleskin or some thick material is then made to cover the whole apparatus, and is tied round the patient's neck. It is important that the cloak should go quite down to the ground all the way round. As the water boils a certain quantity of steam is enclosed within the cloak, and a little later the vapour of the calomel as it rises passes through the steam and becomes mixed with it. The water first disappears, and the calomel is sublimed in from ten to fifteen minutes. The patient then gets into bed with the cloak on, so as to make it his night-dress. In this way the calomel is necessarily kept on the surface of the skin. The cloak used is furnished with a cane hoop, so as to be kept away from the skin during the action of the bath, and this hoop may be removed as soon as the bath is over, and replaced again before the bath is used the next night. The cloak has a slit in front, which the patient is generally directed to open for about an inch, so as to allow some of the vapour to escape. This rises in front of his mouth and nose, and he is directed to inhale it for a minute, at the expiration of each five during the continuance of the bath, so as to breathe the vapour for about three minutes altogether. The patient during this time keeps his head up, so that the moistened calomel vapour passes for about six inches through the common air before it is inhaled. This inhalation is not always necessary, but it furnishes a means of regulating with the greatest nicety the action of the mercury, as indicated by its effects upon the gums. I have never found mercury administered in this way produce salivation where patients had not also taken it in some other form. The action is upon the surface of the body, and the internal parts are comparatively unaffected. No diarrhœa is produced except from some accidental cause. The stomach and intestines are not irritated, and are free for the use of food or medicine. The perspiration produced amounts only to a slight moisture on the skin, and when this is the case the patient very rarely experiences any debilitating effects from the continued use of the bath. During this treatment I generally recommend patients to abstain from taking vegetable acids; and for this purpose, as a rule, they are told not to eat raw vegetables or raw fruits—such as salads, cucumbers, celery, apples, pears, and oranges. As the object is to have the calomel in contact with the skin, the patient washes only as much as may be necessary. Boerhaave long ago made the observation, that if patients went about their usual occupations, and followed their usual pleasures, he could not cure them; and Pearson, as has been stated, found that, under any plan of treatment, if the patients were much exposed to cold air, the effect of his remedies was materially interfered with. This will be the case with regard to any plan of treatment by which there is a fair prospect of really curing the disease. I know how often it has been asserted that the disease is not cured; but a long experience now enables me to say very positively, as I have before remarked, that numbers of patients, after having gone through a proper course of treatment, pass five, ten, fifteen, or twenty years without any fresh manifestations. They believe themselves to be cured, and whatever impression may be left upon their constitutions, no inconvenience subsequently arises either to themselves or their families. In this sense, then, syphilis may be cured, as well as any other recurrent fever to which the human body is liable.

But to effect this, as I have intimated, with any degree of certainty, the action of the medicine should not be interfered with by a diet that is likely to produce diarrhœa, or by exposure to fresh air or cold water. Fresh air has long been known as the antidote to mercurial action; and dabbling in water, either hot or cold, not only washes the calomel off the skin, but its evaporation chills the surface of the body, and, certainly, according to my experience, prevents the full action of the bath as I have described it.

If a patient wants a wash, he may have two or three times a week a warm bath, and remain under the water as long as he pleases. There is then no evaporation from his skin, and he should dry himself as quickly as may be when his warm bath is finished. These are matters of minute detail, but upon their observance or otherwise the success of the treatment of many a case will depend. During the first period of treatment I generally recommend a patient not to be in the open air more than an hour a day, and to select the best part of the day for the purpose, but I seldom object to his going about any ordinary in-door occupation. When the mercurial action is once established, and towards the end of the course, a greater degree of liberty may be allowed. The effect produced is usually a slight feeling in the gums, some increase of saliva, and a kind of metallic taste in the mouth. The gums sometimes become red and swollen, and some pain is experienced in biting a hard crust. All the beneficial effects of mercurial treatment may be obtained by the amount of action indicated by these symptoms, and I seldom, if ever, produce more. The time required for a mercurial course is a question of much interest and importance. This will necessarily vary, according to the nature of the case. We have before seen that the manifestations of syphilis vary very much at its different periods, and that the disease is modified in a very important degree when it recurs. Under these varying conditions the mercurial treatment must be varied also, but there is no phase of syphilitic disease, in my opinion, to which it is not applicable.

By the use of the calomel vapour bath, as I have described it, the evils resulting from the internal use of mercury, and the inconveniences attending inunction, may both be avoided. The remedy may be continued every night, as long as necessary, without danger of depressing the powers of the patient's constitution, without salivation, and without disturbance of the digestive organs. The remedy is applied directly to the parts where the disease, in its primary or secondary forms, usually manifests itself. The slight action maintained on the skin prevents any great determination of blood to other parts, and is in itself beneficial. The plan involves a certain amount of trouble, and the same care with regard to exposure to air and moisture as other modes of treatment do, but it has not their injurious consequences. The whole surface of the skin of the body, and generally the mucous membrane of the nose and mouth, are used for the action of the remedy, and consequently there is no irritation of any one particular part. The action of the skin also in some measure prevents any undue effects of the remedy on the gums, as may also be observed in the administration of the Plummer's pill. This remedy very rarely produces much effect upon the mouth, as the antimony which it contains determines its action rather to the surface of the body.

In the forms of the disease affecting the skin, and characterised by the adhesive inflammation, whether primary or secondary, patients will bear well any form of mercurial treatment, at least for a time. If we have syphilis alone to deal with, at whatever period after infection, the disease is one, and the treatment the same. If the patient is of a strumous constitution; if he has previously been debilitated by prolonged, irregular, or injudicious courses of mercury; if he has suffered from ague, or some other form of fever; or if he has had disease of the liver, spleen, or some other internal organ, then mercury, whether in what have been called the primary or secondary forms of syphilis, must be administered with caution.

Mr. Pearson found that rather a shorter course of mercury was required for primary syphilis than for secondary. I have found, on the other hand, that a longer course is required for primary than for secondary disease. It is probable that, as the diagnosis between real syphilis and local forms of the venereal disease was not made with the same accuracy in Mr. Pearson's time as at present, some cases that were not really syphilitic were included among those which were treated with mercury. These would for the most part get well rapidly, and would reduce the average time during which the treatment was continued. It would, however, be a great mistake to suppose, although no accurate account was then published with regard to affections which would, and those which would not, be followed by constitutional disease, that therefore the older surgeons had not the practical tact of at least distinguishing some of these.

The late Mr. Walker recognised what he called the gonorrhœal sore, and which, to my eye, and as far as my memory serves me, corresponded to what I have described as the local suppurating sore. It is true that many surgeons subsequently, and even in the present day, profess not to be able to distinguish an infecting from a non-infecting sore. Thus, Mr. Cutler, in the evidence before the commission previously referred to, says:—"My opinion is that no one can tell from the appearance of the sore, without the history of it, whether it is infectious or not; that is to say, take what is defined to be the Hunterian chancre, my belief is that in the case of any sore on the penis, if you irritate it, you may convert it into a sore having all the appearances of the confirmed Hunterian chancre; and so strongly do I feel upon that, that at the present time I never determine, in considering the treatment, to administer mercury until I have heard clearly the history of the case."

Now, in spite of the difficulty which formerly existed, and still exists, with some surgeons, of distinguishing an infecting from a non-infecting sore, I am firmly of opinion that the older surgeons did not give mercury in the indiscriminate way that has been supposed; but still that they did give it in some cases where it was not necessary, and that the average period during which it should be continued for primary syphilis was therefore made to appear much shorter than at present. Another point, which was not formerly accurately considered, has tended to the same result: there is seldom a distinction drawn in the writings of the older surgeons between a disease treated for the first time and one which had recurred in a modified form. The latter would be very much more easily dealt with, and require a much shorter period of treatment.

For primary syphilis occurring in a patient for the first time, uninfluenced by the existence of previous disease in himself, or by hereditary influences of the same kind, I seldom now discontinue the treatment under three months, and I generally explain to the patient, to begin with, that unless he is prepared to follow such a course, he had better wait until the secondary symptoms appear, and then undergo his treatment. It is often difficult to persuade a patient who has a slight induration, accompanied by the existence of amygdaloid glands, that his affection is of a nature to require such a course. He will probably ask some friend before he consents, and not unfrequently it has happened in my experience that he has been told that it is "nothing," and has waited until he has become practically convinced of the truth of the diagnosis. This occurred in the celebrated case of the late Mr. Wyndham, which I need not mind alluding to, as the facts were published over and over again in the daily papers. I told him that he not only had the disease, but that he might communicate it. He replied, "Well! I am told it is not so." I did my best to persuade him, but in vain, and, as was soon after given in evidence, he infected his wife. When a patient consents to undergo a proper course of treatment, I generally make him take a calomel bath in the way I have described every night.

Some slight evidence of mercurial action generally appears on the gums within the first week, and this is steadily maintained, either by the calomel bath alone or by the addition of some other medicine. After this action has been kept up for seven or eight weeks the patient is allowed more liberty, but the mercurial action is never allowed entirely to subside, and no break in the treatment is permitted. If the action of the mercury once entirely goes off, it is exceedingly difficult to establish it again in a satisfactory manner. Should this be attempted by increasing the quantity of mercury, the action reproduced will probably not be of the same satisfactory kind. The gums, instead of becoming slightly spongy and soft, will perhaps ulcerate, and there will be some general disturbance of the patient's system. In the treatment of a primary affection, all induration at the site of the original disease should disappear, and, if possible, the amygdaloid condition of the glands. This last, however, is an effect which it is sometimes exceedingly difficult to produce, and some enlargement of the inguinal glands will occasionally remain, in spite of any treatment, for some years, but often without any other manifestation of the disease.

In all secondary forms of skin disease characterised by the adhesive form of inflammation, the same mode of treatment may be pursued, in combination perhaps with some other medicines, of which I shall have to speak.

When a patient's constitution has been weakened from any cause, especially from a continuance of the disease, the eruptions on the skin will change their character. Different forms of eruption may be observed in the same patient at different times. An eruption which is at first papular, and which terminates then by desquamation, at a later stage will be papular or tubercular, and each papule or tubercle will present a white spot of lymph on its apex, which becomes converted into pus. A great many modifications may now occur. In some cases the papules or tubercles, either separate or in groups, remain in a chronic indolent stage, presenting little change from day to day; in others, the action on the skin and elsewhere passes rapidly into suppuration, ulceration, or even mortification. These different results have been distinguished by different names, which are convenient for the purpose of description, but which, in my opinion, would lead to error if made use of so as to imply that these different accidental results constituted so many different diseases. But, nevertheless, each phase, in the development of a syphilitic disease, may require a modification of treatment.

A FACT BEARING ON THE ETIOLOGY OF CHOLERA.

By HENRY BLANC, M.D., M.R.C.P.,
SURGEON-MAJOR HER MAJESTY'S INDIAN ARMY; SUPERINTENDENT YERROWDA CENTRAL GAOL.

THE Yerrowda Central Gaol is situated in the Deccan, some 1865 feet above the level of the sea, and distant some four miles N.N.W. of the town and camp of Poona. The slightly undulated plateau on which the gaol is built consists mainly of trap rock; the country around is bare, a few mimosæ and euphorbiacæ alone cast their scanty shade over the bleak and exposed locality. It is naturally well drained, the nearest village is a mile distant, and from the central tower of the gaol the Moola river can be seen winding right and left about a mile on each side, and marking with its blue line the limits of the peninsula on which the gaol has been erected.

Some large wells and tanks (former quarries) exist in the vicinity of the gaol, but they are used only for agricultural and building purposes. Quite recently water was brought to the gaol by iron pipes from a lake near Poona; before that the drinking water for the prisoners was obtained from the Moola river before its southerly curve—i.e., before it became polluted by the towns of Kirkee and Poona, around which it flows.

The heat during our last hot season was excessive and unusual, at the same time the diurnal range was considerable. During the month of May, in the shade, the maximum varied between 100° and 106° Fahr., and in the sun from 115° to 126°. The nights and mornings were relatively cool, the minimum in the shade being 72° to 75°. The weather was remarkably dry, the rainfall during March, April, and May being 1 inch and 72 cents., and the number of days on which rain fell during three months only three.

The season did not, however, prove unhealthy, and the admissions into hospital fell below the average; cases of febricula due to exposure to the sun, and slight surgical cases, formed the large majority of admissions, and diarrhœa did not prevail above the average of former years at that season.

At 2 A.M. on the morning of the 27th of May a case of cholera, the patient being in a state of collapse, was taken to the gaol hospital; and by noon on the following day twenty cases had been admitted. These cases came from both circles then occupied, and from nine different barracks, and to all appearance this sudden outbreak was general; but a searching inquiry soon made it evident that the epidemic was as yet limited to a certain number of prisoners who had lately been employed in making a new road from the gaol towards the Moola river, there to join the Poona road; and the first impression of a general outbreak was due to these men being quartered in different circles and distributed among the several barracks.

I do not intend mentioning here the steps taken to arrest the progress of the disease, as I wish to limit myself to the cause of this outbreak; it will be sufficient to state that they were vigorous and carefully carried out, and attended with such success that only two cases occurred from among prisoners who did not belong to the gang of men mentioned above.

The following table will show the principal features of the outbreak of cholera we are considering:—

Date.	Number of cases.	Number of deaths.	Number of recoveries.	How employed.	
				Road gang.	Otherwise employed.
May 27th	7	5	2	7	—
„ 28th	13	2	11	13	—
„ 29th	2	1	1	1	1
„ 30th	1	—	1	1	—
June 1st	1	—	1	—	1
Total... ...	24	8	16	22	2

A few words on the two cases that occurred inside the gaol before examining the interesting and important question of the appearance of cholera among the road gang.

The first case of cholera that occurred among prisoners "otherwise employed" was on the 29th of May. This man was sleeping on the night of the 26th–27th near one of the cases that occurred on that night. The suddenness of the outbreak took everyone by surprise, and much time was required before the cholera cases could be removed. It is not improbable that this man may have been infected by the choleraic discharges, as the patient not only vomited in his vicinity, but passed before him each time he had to resort to the night privy. The second of these cases occurred in a prisoner who had been attending on cholera patients. Contrary to orders, this man took his meals inside the cholera ward, and drank of water that had been standing there. In his case direct infection cannot be doubted.

These two secondary cases disposed of, I will now describe the conditions under which cholera made its appearance among the prisoners who had been working on a certain road during the previous days.

The subjoined tables show the occupation of the prisoners on the days preceding the outbreak:—

A.—*Prisoners engaged in intra-mural labour.*

Date.	Excused from labour.	Gaol servants.	Factory.	Miscellaneous.	Total.
May 24th	59	172	301	16	548
„ 25th	53	172	304	12	541
„ 26th	57	174	310	13	554

B.—*Prisoners engaged in extra-mural labour or in out-door labour in Gaol enclosure.*

Date.	Gaol servants	Public Work Department.	Gaol repairs.	Garden.	Thatching roofs.	Road gang.	Total.
May 24th	161	370	10	42	87	61	731
„ 25th	161	373	10	42	18	134	738
„ 26th	163	376	10	42	18	116	725

These 1279 prisoners, as a body of men, can in many respects be considered as a unit; they have the same diet, the same clothing, dwell in the same locality, are exposed to the same meteorological influences, &c.; they differ, and that slightly, but in one respect, according to the labour in which they are engaged.

From the tables given above it will be perceived that of the total number of prisoners about 554 worked under cover. But cholera broke out among those who had been working in the sun, and as this cause might be deemed to have had some influence on the development of the disease, this group of 554 men will be eliminated, and the inquiry limited to the second group of 724 men, who were all of them equally exposed.

Some of the men belonging to our second group were engaged on masonry; some in dragging heavy water-carts along a bad road, and supplying the jail with water; others were engaged in ploughing, or in garden work, or conveyed the night-soil outside the gaol, &c.; and some in watering and rolling a new road. None of these occupations are one more than the other "cholera-producing," and when we find that among this group of men only a certain number contract the disease, we must seek for an explanation beyond telluric influences, cholera waves, absence of ozone, &c.

Now if the men among whom cholera appeared were on no single point differently placed from the other, with but one remarkable exception, this fact must necessarily carry great weight with us, and assist us in solving the arduous question of the etiology of cholera. All the prisoners, whether engaged in intra- or extra-mural labour, were supplied with water taken from the Moola river before it reaches Poona; "the only exception occurred among the prisoners engaged in road work, who drank water taken from the bed of the Moola river below the dam."

It will be observed by a reference to the table of employment that the road gang was considerably increased on the 25th and 26th May; the road had already been metalled, and the extra hands were required to water and roll the road, so that it might not be damaged by the daily expected heavy rains. It should be here stated that a certain number of barrels for storing water and water-carts were sent with the road gang, and that water for drinking purposes was brought to them from above the dam. Five water-carts had been also sent with these men for the purpose of watering the road whilst it was being rolled by others; these carts were filled from the nearest water obtainable—that is, from pools in the nearly dry bed of the river, opposite to the Poona end of the road under construction. The prisoners admitted that they had drunk freely of that water, not only when they filled the carts, but also when they were made to wash before returning to the gaol after their day's task was over. The cholera patients to whom this query was put all unhesitatingly declared that they had partaken freely of it; moreover the warder who was in charge of the carts for supplying them with drinking water corroborated the fact in a remarkable manner; he stated that on the 25th and 26th of May he had conveyed to them less water than on the previous days, although the number of prisoners at work on the road was nearly three times as great. "The fact of the road gang drinking water taken from a source different to the one used by the remainder of the prisoners is placed beyond any doubt."

Was cholera communicated to these prisoners through the water they drank? This is the question I will now endeavour to solve.

On the morning of the 29th May Mr. Taylor (the gaoler) and myself visited the locality from which water for watering the road had been taken. The identical spot was shown to us by the warders on duty on the 25th and 26th, and their testimony was corroborated by our finding there several pieces of gaol clothing. Some 600 or 700 yards above this spot the river is barred; a dam was erected there some years ago for the purpose of securing a constant water-supply to the city of Poona, the river generally running nearly dry during the hot weather. The bed of the river from the dam downwards contained but little water; where we were standing we saw several large semi-stagnant pools, separated from similar small expanses by hugh boulders and moss-covered islets of volcanic rocks; slowly flowing streamlets connected these pools one with another, but on our side of the river-bed the current was so weak that we almost doubted its existence. Between the locality on which we were standing and the dam a number of washermen were at work; men and women were seen here and there performing their morning ablutions, &c.; cattle were roaming about; and a glance showed that the bed of the river between the dam and the place from which water had been taken for watering the road must be contaminated by excreta of all kinds. The river was not overflowing the dam on that day, and from inquiries we learnt that it had not done so for several days: one of the sluices was open, but on the opposite (Poona) side of the river. Water was taken from the pools above mentioned and forwarded to Dr. Gray, the chemical analyst to Government.*

Cholera existed at the time throughout the province, in Poona, and in the neighbouring villages. In India the bed of a river in the vicinity of a large city is the usual place selected by travellers before entering the town to perform their ablutions, &c.; washermen are constantly at work in the same locality; in fact, we could hardly expect to find anywhere so many agencies united to contaminate drinking water by means of choleraic discharges, and, irrespective of what the inquiry had already allowed us to surmise, we would have already strong grounds for accepting the outbreak as due to the propagation of cholera through drinking water. In this instance, however, we possess evidence still more direct and positive.

On the 22nd of May two fatal cases of cholera occurred in the village of Yerrowda, situate opposite the dam, and we learnt that on the evening of the 22nd these bodies were washed and burnt, and the clothes worn during their fatal illness washed some twenty yards above the spot from which water had been drunk by most of the road gang, and which proved so poisonous and so deadly to many of them.

Poona, July 1st, 1875.

REMARKS ON THE

ANATOMY AND PATHOLOGICAL RELATIONS OF A NEW SPECIES OF LIVER-FLUKE.

BY J. F. P. McCONNELL, M.B.,
PROFESSOR OF PATHOLOGY AND RESIDENT PHYSICIAN,
MEDICAL COLLEGE, CALCUTTA.

ON the 9th of September, 1874, I made a post-mortem examination of the body of a Chinaman, and found in the liver, obstructing the bile-ducts, a large number of "flukes." A careful examination of these, and comparison with other known distomata, have convinced me that they not only differ from the ordinary liver-fluke (*Dist. hepaticum*), but constitute an entirely new species. I desire therefore to describe the salient anatomical characters of these flukes, then to give a brief account of the post-mortem examination alluded to, and lastly to make a few remarks upon the case.

The woodcuts which accompany this paper will facilitate the description. Fig. 1 represents a few of these flukes drawn to natural size. Fig. 2 is one specimen enlarged to about six times the natural size, showing the ventral surface. Fig. 3 represents the ova magnified 300 diameters.

FIG. 1. *Ad. Nat.*

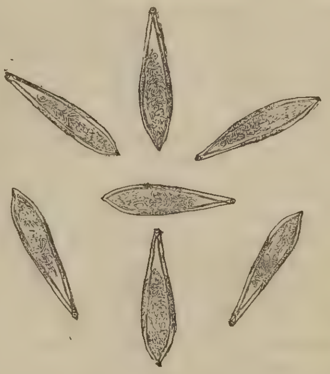


FIG. 2. × 6.

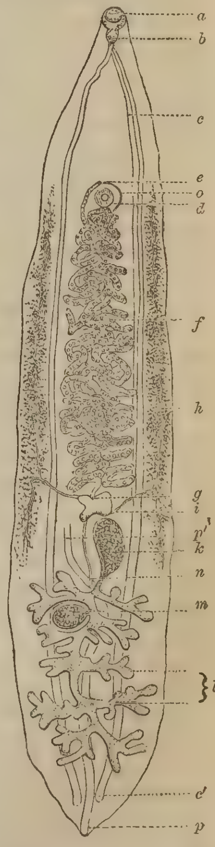

FIG. 3. × 300.

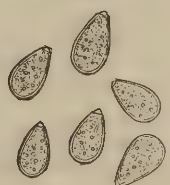

Fig. 2.—*a.* Oral sucker. *b.* Œsophagus. *c, c'.* Right alimentary canal. *d.* Ventral sucker. *e.* Genital orifice. *f.* Uterine folds. *g.* Ovary. *h.* Vitelligene gland (right). *i.* Vitelligene duct (right). *k.* Right testicle. *l.* Receptaculum seminis (?) *m.* Left testicle. *n.* Vas deferens. *o.* Termination of vas deferens. *p.* Pulsatile vesicle. *p'.* Water-vascular canal.

The body is narrow, flattened, lanceolate; the central portion being the broadest part of the animal, the anterior and posterior extremities tapering and pointed, the former, however, being much narrower than the latter, which is more strictly ovate. The surface of the body is smooth, quite free from hairs or spines even in the fresh condition. The borders have a slightly undulating outline. At the anterior extremity (Fig. 2) is situated the oral sucker (terminal), *a*—a hollow disc, provided with a well-defined sphincter. At the bottom of this cup-like cavity is the mouth; this leads into the pharynx, *b* (which is circular or slightly oval-shaped, and is probably muscular), and thence into the œsophagus. The œsophagus bifurcates in the median line of the body (a little distance above the ventral sucker) into two alimentary canals, *c*, which diverge as they pass downwards and outwards along the sides of the body, slightly widening as they proceed, and converge again towards the caudal extremity, close to which they terminate in blind cul-de-sacs, *c′*. These canals are unbranched throughout. On the inferior surface of the body is the ventral sucker, *d*; situated in the median line, and about $\frac{1}{6}$" (one-sixth of an inch) below the oral sucker. It is imperforate, and provided with a sphincter, the radiating fibres of which can be clearly distinguished. This sucker is slightly smaller than the oral, measuring $\frac{1}{34}$", whereas the latter is $\frac{1}{25}$".

---

* Analysis of the water made by Dr. Gray, chemical analyst to Government:—Solid grains per gallon, 10·36; chlorine, ·95; hardness, total, 6·30; hardness, permanent, 3·42; oxygen removed by readily oxidisable matter of water at 140° F., ·072. Part per million of free ammonia, 0·32; of albuminoid ammonia, 0·22.

Just above the ventral sucker is a minute dark dot, *e*, which appears to be the genital orifice. No penis or penis-like appendage can be detected, but ova have, in several specimens, been seen to assume a linear arrangement between the little orifice just mentioned and the hollow ventral disc into which they have dropped. Opening into this genital orifice, in favourable specimens, can be traced the delicate tubular termination of a convoluted uterine tube. This structure is highly developed, and consists of a series of very intricate windings, *f*, which communicate posteriorly with a flattened, somewhat square-shaped body, the ovary, *g*. The uterine tubules are semi-opaque, but in the more transparent portions numerous ova are seen collected together within the folds. The uterus and ovary occupy rather more than the middle third of the animal.

Occupying the interspaces between the alimentary canal and the lateral borders of the body on either side are the dark, pigmented-looking structures, the vitelligene structures, *h*. These communicate with the ovary by two delicate canals, which run transversely inwards to it, and constitute the vitelligene ducts, *i*.

Placed a short distance behind the ovary is a large oval-shaped body, the testis, *k*; which is succeeded by a remarkable and peculiar development of branched, dendritic-looking structures, *l*, among which, in several specimens, a rounded smaller testicle (*m*) can be distinguished. This apparatus appears to be connected with the male generative organs, and forms perhaps a kind of receptaculum seminis. This is the most marked and distinguishing character of this fluke. The testes and branched receptaculum are of a rusty-brown colour, both of the same tinge,* and have granular amorphous contents; the connexion, however, between this apparatus and the testes is uncertain, but, as far as one can speak from a very careful examination of several specimens, the arrangement is that which has just been briefly sketched. The position and shape of the second or smaller testicle are also very variable. In some of the parasites only one large globular organ of this kind can be discovered; in others, the position of the second testis is lower down the axis of the receptaculum; in others again, instead of a distinctly rounded organ, a mere diffuse "blurring" of one of the branched tubes can be held to represent this second testicle.

Starting from the upper part of the male generative apparatus, a very delicate thread-like structure can be seen, *n*, which runs upwards by the side of the larger testis to the lower border of the ovary, and probably above it, but can be traced no further. This appears to be the seminal efferent duct, or vas deferens. The point at which it communicates with the female generative apparatus was not for a long time ascertained; but lately, in a specimen stained with carmine, and then *pressed* between thin pieces of glass, I have been able to discover (what seems to me the continuation of this tubule) a very delicate structure, *o*, curving round the ventral sucker on the *opposite side* to the termination of the uterine folds, and ending at the same genital orifice, or at a point very close to it, as depicted in the engraving (Fig. 2). As this tubule is a flexible elastic structure, it may very possibly run up the same side as the uterine tubule, and not occupy an opposite position; I have drawn it, however, exactly as seen in the specimen alluded to.

Lastly, at the caudal extremity of the body of the fluke may be seen a pulsatile vesicle or bulb, *p*, associated with the water-vascular system of the animal; the continuation of the same upwards, in the form of a vascular canal, can be traced for a certain distance, passing above the male generative apparatus in a winding course, and being lost sight of at a short distance to the left of the right testicle, *p′*. The average length of the distoma now described is $\frac{7}{10}$", and the breadth $\frac{1}{7}$". The latter is very constant; the former has slight variations—viz , from $8\frac{8}{10}$" to $\frac{6}{10}$".

I have not observed any further marked peculiarities in the minute structure and arrangement of the tissues and organs of this particular parasite but what have been described by systematic writers on entozoa; so that I refrain from adding unnecessarily to the length of this paper by giving detailed accounts of microscopic appearances already well known.

The ova are of distinctly ovoid shape (Fig. 3). A short distance from the more pointed extremity is a dark, transverse line, just as is usually seen in the ova of distomata, and indicating the line of contact of that lid-like organ or operculum, which, after a time, spontaneously separates. The average length of each ovum is $\frac{1}{833}$", and the average breadth $\frac{1}{1666}$"; thus, roughly speaking, it is twice as long as it is broad.

The individual from whose liver these flukes were obtained was a Chinaman, aged twenty, a carpenter. He was brought into the Medical College Hospital at midnight on September 8th, 1874, in an insensible, moribund condition. The only history that could be obtained from the "friend" who accompanied him was, that the patient had been suffering from "fever" of a continued type for about a fortnight. The insensibility was profound; the pupils were normal; the conjunctivæ looked pale. There was considerable dyspnœa; a hard, tense, distended, and slightly tympanitic condition of the abdomen; a hot skin, and an almost imperceptible radial pulse. He never rallied, but died, in much the same state, two hours and a half after admission.

A post-mortem examination was made the next morning, five hours and a half after death, a brief summary of which is as follows:—Body fairly nourished; pupils dilated; conjunctivæ jaundiced; rigor mortis strong in the lower limbs. The dura mater yellow-stained; vessels of pia mater everywhere gorged with dark blood, slight serous effusion also into its meshes; cerebral substance moderately firm; puncta large and bleed freely; grey matter of both cerebrum and cerebellum particularly dark—a deep leaden hue, such as is met with in many of the severe remittents of this country. The large pulmonary vessels at the roots of the lungs contained much fluid dark blood, but the lung-substance everywhere else was rather pale and anæmic—structurally healthy. One ounce of deeply yellow-tinged serum was found in the pericardial cavity; a few dark clots and fluid blood in the right chambers of the heart; the left were almost empty. The peritoneum was healthy, and no effusion was found into the abdominal cavity. The liver was large, swollen, and tense; superficially of a dark-purple colour, on section paler, more dingy or muddy-looking. Its parenchyma everywhere very soft. The large portal and hepatic veins were filled with fluid blood, and the bile-ducts particularly distinct from their large size, and distension with thick yellow bile. On incising the liver in different directions it was noticed that small, dark, vermicular-looking bodies escaped on to the table, and on more careful examination these were clearly seen to protrude from the bile-ducts, which, on being dissected, were found more or less obstructed by and containing them in large numbers, some lying free, others coiled up, and either solitary or in groups of twos or threes within the biliary ducts; all were dead. The gall-bladder was full; the cystic and cholodic ducts were patent. The bile in the bladder was of a very deep yellow (orange) colour, thick, and measured about an ounce and a half. No distomata were found in the gall-bladder, nor were any ova discovered on microscopical examination of the bile and lining membrane of this sac. Numerous ova and shreds of epithelium were found in the biliary canals. (The weight of the liver after incision was 54½ oz.) Portions of this organ were hardened, thin sections made, and examined microscopically. A most remarkable and intense pigmentation of the parenchyma was observed—not mere staining, but a positive infiltration of black pigment, granular in character, and not confined or specially distributed in the interlobular tissue, but occupying the hepatic cells also within the lobules; the greater portion being disposed in the form of minute, very dark, granular depôts, from which smaller molecules radiated in all directions as from a centre. The pigment matter appeared to be biliary rather than hæmatoid. Many of the hepatic cells were also infiltrated with fat, and the nucleus in the majority was ill-defined or altogether indistinguishable. The spleen was found enlarged; its capsule stretched, slightly thickened, and opaque; its substance very dark and pulpy; weight 13¾ oz. The kidneys were moderately hyperæmic and dark. The small intestines were found deeply bile-stained; the large, natural. The fæcal contents of both—partly solid and partly liquid—were bile-coloured, but no distomata were found in them, although carefully washed and examined.

---

* In the diagram the engraver has made the testicles darker than the rest of the apparatus, and their contents somewhat largely molecular, but this is not correct.

Remarks.—The morbid anatomy of the liver in this case seems unequivocally to point to the presence of the flukes in its biliary ducts as the exciting cause of the acute and extensive structural degeneration of the proper structure of the organ, and of that cholæmic condition induced by the obstruction of the biliary channels which appears to have been the immediate cause of death. It is noticeable that the gall-bladder itself contained no distomata, nor exhibited any evidences of having been occupied by them, while the bile-ducts were found densely crowded. I must have collected at least thirty specimens in my dissections, and numbers doubtless still remain in those portions of the liver which I have preserved entire, for hardly any duct of medium size has not been found to contain two, three, or more of these parasites.

The discovery of this distoma may perhaps throw some light upon the pathology of those obscure liver enlargements and jaundices which every now and then, in this country at any rate, are presented to the practitioner; and although I never met with an analogous case, yet I can recall to memory a few instances during the past three years, of Chinamen especially, many of whom are settled in this city, who have applied to me in the medical out-patient department of this hospital for the treatment of obscure, hard, massive enlargements of the liver, with or without jaundice, and in whom I am now naturally inclined to suppose that a similar cause for the disease might have existed.

The Chinese as well as the Burmese are well known to be "filthy feeders," delighting in putrid messes of half-raw fish, &c.; they are bound by no caste prejudices (as the natives of India are) to abstain from any kind of "flesh, fish, or fowl"; they partake, moreover, of all kinds of "vegetable food." The sources from whence the larvæ of such parasites may be derived are therefore not far to be sought. In the present instance, I regret to say, I have been unable to gain any information as to the antecedent history and habits of the deceased. The "friend" who brought him to the hospital never reappeared, and the body after death was "unclaimed." With reference, however, to this question, my attention has been directed to a paper by Professor Leidy, of America,[*] who reports that he had received from Dr. J. G. Kerr, of Canton, China, a worm which "was vomited by a Chinese boy, aged fifteen, and brought to him" (Dr. Kerr) "an hour and a half after its expulsion, when it was still alive. It had the appearance of a leech, and was red in colour, about an inch and a half long, and three-quarters of an inch where widest. Dr. Kerr also stated that a girl of four years, of English parents, living in Canton, passed from the bowels at one time nine of these worms. With these exceptions Dr. Kerr had not met with anyone who had ever seen or heard of anything of the kind." Prof. Leidy is of opinion that this parasite is a true liver-fluke. He says: "The worm exhibits some differences from D. hepaticum as usually described, but perhaps not sufficiently to characterise it as a distinct species." The specimen had been preserved in strong alcohol, which had doubtless contracted and reduced it in size, "but it is yet larger than the size assigned to D. hepaticum. It is perfectly smooth throughout, and exhibits no trace of roughness to the integument. It is ovate-lanceolate in form, and gradually widens from the anterior to the posterior rounded extremity. The ventral acetabulum is twice the size of the mouth, and is situated about its own diameter behind it. The genital organ with the exserted spiral penis is placed just in advance of the ventral acetabulum. The measurements of the worm in its present condition are as follows:—Length, 17 lines; width at the posterior third, 7 lines; thickness near centre, 1 line; diameter of mouth, $\frac{2}{5}$ line; diameter of acetabulum, $\frac{4}{5}$ line."

With respect to the identification of the distoma found by me, I have carefully and diligently searched such works as are here accessible (works of reference being very few and with difficulty attainable in this country), especially the classical helminthographs of Dr. Cobbold,[†] of Van Beneden,[‡] and of Leuckart,[§] but have been unable to find the description of any distoma which possesses the anatomical peculiarities that distinguish the one now under consideration. That it is not the ordinary D. hepaticum there can hardly be any doubt. It is more closely allied to the D. lanceolatum of Mehlis; but, apart from certain differences in size and general conformation, there are very important differences in the position and construction of the male and female reproductive organs between these two species. To enter into an account of these minutely would occupy too much space, and, moreover, does not coincide with the primary or principal object I have had in view in the publication of the history of this case. I have been moved thereto more by pathological than purely anatomical considerations; nevertheless, I think I may be able to express my impressions with respect to the latter by exhibiting in a tabular form some of the more prominent differentiating peculiarities of these three distomata.[||] Thus:—

	D. Hepaticum.	D. Lanceolatum.	New Liver-fluke.
Length	$\frac{3}{4}''$ to $1''$.	$\frac{1}{3}''$ (8-9 mm.)	$\frac{7}{10}''$.
Breadth	$\frac{1}{2}''$ to $\frac{2}{3}''$.	$1\frac{1}{2}'''$.	$\frac{1}{7}''$.
Oral sucker	Smaller than ventral.	About same size.	Larger than ventral.
Integument	Covered by minute spines.	Smooth.	Smooth.
Intestinal canal ...	Branched.	Not branched. Terminates at lower fourth of body.	Not branched. Extends through the whole length of body to the caudal extremity (nearly).
Male reproductive organs	Form a series of spread-out vermiform tubes.	Form two distinct globular testes, placed one above the other in the median line *directly below* the ventral sucker.	Form one or two globular testes, occupying the lower third of the body *below* the female reproductive organs, and are connected with a very remarkable development (receptaculum seminis?).
Female reproductive organs	......	Occupy central and hinder parts of body *below* the testes.	Occupy the anterior and middle third of the body *above* the testes and seminal apparatus.
Ovum...	$\frac{1}{180} \times \frac{1}{270}$.	About $\frac{1}{600}'' \times \frac{1}{833}''$.	$\frac{1}{333}'' \times \frac{1}{1666}''$.

[||] I need hardly refer to the D. conjunctum of Cobbold. Although the anatomical "arrangement of parts" in this little fluke has a somewhat

In conclusion, I have to acknowledge my great indebtedness to my friend Dr. T. R. Lewis, who has afforded me much kindly assistance and encouragement throughout this research, and I would add that I intend to forward by the earliest opportunity to Professor Parkes, of Netley, a portion of the liver and several specimens of this distoma for the museum of the Royal Victoria Hospital.

Calcutta.

CASE OF

POPLITEAL ANEURISM CURED BY AN EXTEMPORISED COMPRESSOR.

By NATHANIEL ALCOCK,
SURGEON, ARMY MEDICAL DEPARTMENT.

M. H——, aged thirty-eight years, wife of a private in the 47th Regiment, was admitted into the Female Hospital, Aldershot, on July 8th, 1875. For more than six months she had felt undefined shooting pain about the right knee, without, however, being incapacitated from her usual employment. On Sunday, July 5th, she went as heretofore to the North Camp chapel, carrying in her arms a child eighteen months old; when descending the incline approaching the chapel she became suddenly conscious of a painful throbbing at the back of the knee, but remained through the service, and subsequently carried home the child. The pain continued through the evening and night of Sunday, yet she went on the following morning to wash at the washhouse; by this the pain was much increased, owing to the labour of carrying water to and fro, and at night it became so intense as to prevent all rest. On Tuesday morning she walked in great agony to the station hospital, and, returning with no little difficulty to her hut, remained lying down in accordance with the directions of the medical officer till the afternoon of the next day, when she was removed to the Female Hospital.

When seen at 6 o'clock P.M. on Wednesday, July 8th, there was an aneurism about the size of a small hen's egg, pulsating very strongly, with a feeling of forcible dilatation at each heart-stroke, as if the sac was very thin. Having in a female hospital neither the command of relays of students as in a civil hospital, nor of orderlies as in a military one, it was impossible to organise a corps of digital compressors. Accordingly, at 7 o'clock, a Carte's tourniquet was applied to the femoral, and pressure maintained with alternately complete and partial control of the circulation for four hours, but could not be continued longer owing to the pain excited. All treatment was omitted for the night.

At 11 o'clock on the day following Carte's tourniquet was again applied, a nurse's finger being made the immediate pad, as that was best borne. A second tourniquet was secured over the vessel at Scarpa's triangle, to be tightened from time to time as a relief to the first. Pressure was thus continued as completely as the patient's restlessness would admit, but was practically only intermittent, for seven hours, when it could be no longer tolerated. No appreciable alteration had taken place in the aneurism; further compression being quite impossible, the leg was at 6.30 P.M. tightly flexed upon the thigh, and left so for the night. Flexion as complete as could be accomplished by lacing the limb up in a kind of leather stays was kept up without a moment's intermission for three days and four nights.

At 10 o'clock on the 12th of July the tumour was again examined, and seemed to have become slightly less expansive, feeling as though the wall of the sac was a little thickened; but the amount gained was so very doubtful as to render the prospect of cure by this means very hopeless. Carte's tourniquet over a finger was resumed; but in an hour and a half the patient became so unmanageable from the severity of the pain that it had to be finally dispensed with, and the limb was again flexed. The treatment of the case seemed now narrowed to two alternatives—either continued anæsthesia by chloroform for eight or ten hours to admit a perfect trial of instrumental pressure, or operation. While endeavouring to decide upon the best course to be pursued, I remembered that Dr. Bellingham had found the weight of a conical piece of lead to be borne when no instrument would be submitted to. I accordingly got from the matron a tin funnel, inserted a cork into the narrow end, and covered this with a soft pad. The funnel was then filled with shot, and the whole enclosed in a conical calico bag to prevent the shot escaping. This was applied at 6 to 8 P.M. without causing much inconvenience. It was then removed, and the limb flexed for the night.

At 9.30 A.M. on the following morning (July 13th), the aneurism being unaltered since last examination, the shot-funnel was placed over the femoral at the fold of the groin, the exact position of the vessel being indicated by a piece of soap plaster, spread on leather, pasted over it, and additional shot was poured into the bag until the circulation was completely stopped; the limb was unbent to relieve the acute pain in the front of the knee, and by the almost incredible patience of the matron and the ward nurse the weight was held in this position for twelve hours and a half without the slightest variation. At the end of that time, to my very great astonishment, all pulsation in the tumour was at an end, and the aneurism cured.

For two days the funnel was applied for a few hours each day to secure the full contraction of the clot, and then was finally omitted. The total weight of the loaded funnel was 6 lb. 2 oz.

The collateral circulation was so effectually developed that the temperature of the limb was not at any time perceptibly lowered, nor has any inconvenience arisen from occlusion of the main artery.

The tumour is now (July 23rd) reduced to the size of a small walnut, and is perfectly solid.

Aldershot.

THE PHYSIQUE OF FACTORY CHILDREN.

By CHARLES ROBERTS, F.R.C.S.,
LATE ASSISTANT-SURGEON TO THE VICTORIA HOSPITAL FOR SICK CHILDREN, ETC.

The evidence given by Dr. Ferguson, of Bolton, before the Royal Commission on the Factory Acts, has produced a deep impression on the public mind, and has been noticed and commented on by The Lancet, *The Times*, and the public press generally. While ready to admit to the uttermost the ill effects on the constitution of children of the substitution of tea and coffee for milk in their diet, and of the degenerating effects of intemperance in the parents, and, worse still, intemperance and the use of tobacco in their progeny, I am disposed to think that Dr. Ferguson very much over-states his case, and for some reason, which requires explanation, his experience of the degeneracy of the factory population is not borne out by wider and equally exact and careful observation; but, on the contrary, there is evidence of the improvement of the physique of the factory children.

In the winter of 1872 and '73 I was engaged with others in investigating this subject, for the purposes of Dr. Bridges's and Mr. T. Holmes's "Report to the Local Government Board on the Proposed Changes in Hours and Ages of Employment in Textile Factories," and I had opportunities of examining, weighing, and measuring many thousands of factory children in Bolton (Dr. Ferguson's town), Bury, Rochdale, and other manufacturing districts, and afterwards of comparing them with the children in York and the agricultural districts in the North Riding; and the following notes, taken at the time and published in the Report, will show the result of that investigation:—

The factory children are fairly well developed, and remarkably free from constitutional diseases; and, with the exception of a disposition to flat-foot and a relaxed state of the ligaments of the knee- and elbow-joints, are free from deformities.

In general conformation of body the factory children do not compare favourably with the agricultural. In the manufacturing towns the children are short of stature, have

---

close resemblance to that in the new distoma, yet its size (about ¼″) precludes at once its being recognised as anything more than an allied species, and *it has never yet been found in man.*

thick limbs and large feet and hands, and are muscular, and in tolerable condition as to fat. They produce the impression on the mind of having bodies too old for their heads (and ages).

Flat-foot, with a general disposition to knock-knee, is very common among the factory children, while both are rare among the agricultural, among whom there is a disposition to the opposite state of bow-leg.*

A few cases of deformity of the chest are noted in the tables as "pigeon-breasted," but they were all of a slight character. A few cases of the opposite state of depression of the sternum came under my notice also; but in no instance did I find a marked rickety affection of the long bones or of the bones of the face.

Scrofula, like rickets, appears to be equally rare among factory and agricultural children. Probably most of the cases of "old scars in the neck" recorded in the tables were the sequelæ of the eruptive fevers, as in most instances no other signs of scrofula existed.

In a large majority of the factory children the gums were red and spongy, but did not bleed, nor were there any other signs of scurvy. It is probable that this state of the gums is due to a deficient supply of vegetables in the dietary of the children. From numerous inquiries made among the children, I learned that they generally had meat and potatoes on three days in the week, and bread-and-butter and tea or coffee with little milk the remainder. The other meals also consisted of bread-and-butter and tea, and not of porridge made of oatmeal and milk as formerly.

The development and condition of the teeth in the factory children was very unsatisfactory. Many of the teeth were of a bad colour, badly shaped, and irregular. Teeth with contracted crowns, serrated edges, and deep perpendicular grooves were common; many were marked with deep transverse grooves, as if a file had been drawn across them, and when caries existed—which was very often—it was generally in the course of one of these grooves. All these imperfections in the teeth point to some fault in the health and nutrition of the child during the early stages of its development, but were not due to congenital syphilis.

The personal habits of the factory children contrast very unfavourably with those of the agricultural districts. They were dirty in both body and clothes, the hair unkempt and almost invariably swarming with lice; an irregular form of prurigo—almost the only skin disease found among them—and marks of scratching on the chest and back pointed to the existence of body-lice also. Few of the children were free from the marks of flea-bites. In all these particulars there was a marked improvement going from east to west, Bolton being the worst and Rochdale the best.

With the exception of the flat foot and the somewhat stunted growth of the children, nearly the whole of the disadvantages the factory children labour under are to be attributed to social causes rather than factory work—causes such as Dr. Ferguson so forcibly denounces, and which the Commissioners regret their inability to meddle with. My picture of the health and physique of the factory children is not, however, so dark and hopeless as his, and I can adduce statistical evidence in support of my position.

The following accounts of the weights of factory children nearly forty years ago—viz., in 1835—and in 1873, show a marked advantage in favour of the children of the present day. I also add the weights of the agricultural and town children not engaged in factory work, which may be considered the maximum standard of the labouring classes; and the weights of some boys in our public and middle-class schools, which we may consider the highest standard of our English race at their respective ages. I add also, for the purpose of comparison, the weights of some boys of the same ages in a London charity school, where they are well fed and have plenty of drill and exercise.

Average Weight in Pounds.

Age last birthday.	London Charity School.	Factory Report, 1835.	Factory Report, 1873.	Agricultural Children, 1873.	Public & Middle-class Schools, 1873.
9 years	51·63	51·76	58·72	60·02	61·98
10 "	54·53	57·0	62·74	65·29	67·2
11 "	58·32	61·84	67·92	71·01	74·19
12 "	62·8	65·97	71·06	75·0	78·98
Number of observations.	1770	160	2958	800	1210

From the table it will be seen that a factory child of the present day, of the age of nine years, weighs more than one of ten did in 1835; one of ten now more than one of eleven then; and one of eleven now more than one of twelve then; and it will be seen also that the factory children even of 1835 were superior to the London children of the present time. I regret that the statistics do not go to the higher ages referred to by Dr. Ferguson, but our investigations were limited to children under twelve years of age, who were employed as "half-timers." The numbers are, however, so regular in their increase for the respective ages that they may be relied on as a test of the general physical improvement of the factory population. The heights and chest-girths of the children are not given in the report for 1835, and Harrison's tables, published about the same time, are useless for purposes of comparison, as they include both sexes. Quetelet's tables, published also about the same time, are, for obvious reasons, inapplicable, as they refer to a different race.

I am inclined to think that the cry of the degeneracy of our labouring population has been too readily assented to by our profession; and, if this were the time and place, I could adduce other statistical evidence of improvement in another class of children; indeed, it is fair to infer that, with cheaper and better food, shorter hours of labour, less gross intemperance, and better sanitary arrangements, our whole English race should be improving in physical condition. I hope Dr. Ferguson will submit to the profession the statistics on which he bases his opinions of an opposite state of the degeneracy of the factory population.

Bolton-row, Mayfair.

CASES OF
RUPTURE OF THE MEMBRANA TYMPANI FROM BLOWS ON THE EAR.

BY SIMEON SNELL, M.R.C.S., &c.

THE publication in THE LANCET recently of Mr. Dalby's interesting cases of injuries to the ear has induced me to record a few brief notes of the following cases, which have come before me during the past year.

CASE 1.—J. N——, aged thirty-three, a turner, applied to me at the Sheffield Eye Dispensary in March, 1874, with a thin purulent discharge from the right ear and defective hearing. On examination, a perforation was visible in the anterior portion of the membrana tympani, and, on inflation, a little muco-purulent discharge escaped through it. He gave the following history:—Six months previously (September, 1873), whilst sparring with one of his companions, his head became firmly locked beneath his antagonist's arm. He struggled to free himself, and when, at length, he succeeded, he experienced a singing and buzzing sensation in the right ear, and found his hearing much impaired. Under treatment the discharge soon ceased, and he was lost sight of for a considerable time. Towards the end of November, however, an opportunity was afforded me of ascertaining the condition of the ear. The rupture had now closed, and the hearing had improved. On seeing him again a short time since, he thought his hearing quite perfect, and was surprised to find he could only hear my watch tick at eleven inches with the right ear, whereas with the left he heard it at thirty-six inches.

CASE 2.—On the 29th of April, 1874, I was requested to see, with a medical friend, a young gentleman about twenty years of age. He stated that on the 17th of the month he had had an altercation with a man, who had violently assaulted him, knocking him down, hitting him on the eye and head, and boxing his ears. When I saw him, in addition to several bruises on the head, there was a long, narrow contused wound of the right cheek, ecchymosis of the left eyelids and conjunctiva, and marks of violence on the auricle of the left ear. The left pupil was dilated; he said he was almost completely blind, and with the ophthalmoscope were discovered several fine capillary hæmorrhages in the retina. A few days later he drew our attention to the left ear, from which, he said, there had been some slight discharge after the assault, with constant buzzing noise, pain, and impairment of hearing. Examination disclosed a large rupture of the tympanic membrane, through which the patient easily blew a current of air. The eye regained its normal appearance, but at the end of July the ruptured membrane was not healed, and, since then, no opportunity has been afforded me of ascertaining its condition.

---

* For statistics and remarks on this subject see my paper on "Flat-foot" in St. George's Hospital Reports, vol. vii., 1874, p. 211.

Case 3.—James M——, eighteen years of age. On November 13th, 1874, he was playing with a companion, who struck him forcibly on the left ear with his flat hand. After the feeling of heat and tingling following the blow had passed off, he noticed a singing noise in the ear, and fancied he could not hear so well. He also suffered pain, and there was a discharge from the meatus of a small quantity of sanguineous fluid. An examination on Nov. 17th disclosed a rupture of the membrane in front of the handle of the malleus, but smaller than in either of the other cases. The rupture soon closed, but his hearing remained defective, and, on recently testing him, I found that while he heard my watch at fifty-six inches with the right ear, it was audible only at twenty-nine inches with the left.

Sheffield.

NITRITE OF AMYL IN SEA-SICKNESS.

By CROCHLEY CLAPHAM, L.R.C.P. L., F.L.A.S., Ph.D.

In recommending the employment of nitrite of amyl as a remedy in the treatment of sea-sickness, I do so with considerable experience of its utility. During a trip round the world of nearly two years' duration, in which time I crossed the Pacific Ocean in various directions no less than eleven times, I made the treatment of this distressing malady my especial study,—with what result will be seen below.

On my way out east I ran through all the prevalent modes of treatment, nice and nasty—such as iced champagne, bottled porter, camphor, chlorodyne, belladonna, ice to the spine, &c.,—and, with the exception of the last-named, found them all merely palliatives, and of very uncertain action even to that extent. With respect to Dr. Chapman's spinal ice-bags, I can report favourably of their use in sea-sickness, when procurable; but people will not or cannot provide themselves with these articles, nor will ship-owners supply them in any number, and nothing can be more futile than attempting to treat twenty or thirty sea-sick people with one or two ice-bags.

As to the proximate cause of the malady, I entirely agree with Dr. Chapman that it consists of an undue congestion of the vessels of the spinal cord. On this point I had an excellent opportunity of drawing some conclusions from a post-mortem which I was fortunate enough to make whilst acting as superintendent of the Government Civil Hospital at Hongkong last summer. The case was that of a Chinaman who had been killed, whilst in the very act of vomiting during an attack of sea-sickness, by the fall of a heavy piece of iron from aloft. I found, on making the necropsy (four hours after death) that, leaving out of consideration the heart, which had been pierced by the falling iron, all the organs were healthy with the exception of the spinal cord, the vessels of which were literally gorged with blood throughout its entire length. I was struck with the similarity of this appearance to that presented by the spinal cord of an epileptic patient who died in the "status," and upon whom I made a post-mortem whilst at the West Riding Asylum, Wakefield. Coupling the post-mortem likeness to the resemblance which obtains in life between these two affections (pallor of surface, cold sweat, &c.), it occurred to me that the remedy which, in the hands of Dr. J. Crichton Browne, has proved so valuable in the epileptic "status," might be advantageously employed in the treatment of sea-sickness.

To test the truth of this surmise I made several trips across the Pacific, and tried the remedy altogether in 124 cases. Of these, 121 proved eminently satisfactory, there being no return of the vomiting after the administration of the nitrite; the remaining three cases being only unsatisfactory in so far as they required a further dose or two of the remedy.

The mode of exhibiting the drug which I adopt is by inhalation, three drops* of the nitrite being poured on a handkerchief and held *close* to the patient's nose. The inhalation must be conducted rapidly, so as to give the full influence of the drug without a *too free* admixture of air.

The action of the remedy in freeing the circulation and relieving the hyperæmia of the spinal cord will be quickly evidenced by a throbbing sensation in the temples (occasionally rather disagreeable) and by a more or less general flushing and increased warmth of the surface of the body. This warm and comfortable glow, which takes the place of the chilly sweat so disagreeable in this disease, is usually followed in the course of half an hour by a pleasant slumber, from which the patient wakes to eat a hearty meal. Should the sickness recur, which it may do after the lapse of twenty-four hours, the inhalation must be repeated. The patient should be in bed when under treatment, so as not to interfere with the subsequent sleep; and I have usually judged it better to allow one fit of vomiting to take place before applying the remedy, not only to ensure the *bonâ fide* character of the seizure, but also because I consider it advantageous unless the patient be in a very weak state of health. I only met with one case in which the medicine was refused on account of disagreeable effects, and in this instance, which occurred in the tropics, the patient complained that "it made him feel so hot he would rather be sea-sick."

In conclusion, I hope my experience of the remedy will be supplemented by that of the "sea-going" portion of the profession generally, and that any further facts elicited regarding its action will be duly published.

Thames Ditton.

A Mirror of HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum, tum proprias collectas habere, et inter se comparare.—Morgagni *De Sed. et Caus. Morb.*, lib. iv. Prooemium.

WESTMINSTER HOSPITAL.

CASE OF SEPTICÆMIA; PERIOSTITIS; PERICARDITIS; DEATH IN THREE DAYS.

(Under the care of Mr. Cowell.)

For the notes of the following case we are indebted to Mr. W. R. Cheyne, surgical registrar.

A school-boy, named Cornelius S——, eight years of age, was admitted into St. Mark ward on the morning of June 11th, in consequence of supposed injury to the left leg. The only clue to the present illness was the statement that the boy had recently trodden on some glass in a dust-bin and cut one of the toes of his left foot. He had been at school up to 12 o'clock on the previous day (June 10th), when he came home complaining of cramp and pain in the knee; and towards evening he became "light-headed." The boy had previously been quite healthy and active. There was some general enlargement of the left leg and thigh at the time of his admission, with hot surface and some tenderness. In the evening his temperature was 104·6°.

On June 12th the skin was hot, the tongue dry, and the mind wandering. There was great tenderness of the limb, with some increase of swelling, especially in the lower part of the thigh, and the least pressure or movement of the limb produced a scream. The swelling appeared to be due to enlargement of the shafts of the femur and tibia, and no fluctuation could be detected. There was a large pustular bleb on the back of the second toe, the position of the original wound, and there was also an excoriation over the inner malleolus.

June 13th.—The temperature rose this morning to 106·4°. The chest became much engorged during the day, but some relief was afforded by an emetic at night. A bleb, similar to that on the toe, having formed on the right little finger, was opened, and discharged chiefly blood and serum.

---

* More should not be used without medical advice.

14th.—The patient had been delirious and restless during the night, but at noon to-day the temperature had fallen to 102·4°. The pulse was about 160, and very weak; the tongue was dry. The lungs were still much engorged, and the respiration had become more difficult, but was easier under the influence of a jacket poultice. The left thigh was less swollen, and there was now considerable œdema and redness over the upper third of the tibia. Later in the day the chest symptoms became more urgent, and the child died at 5.35 p.m.

The treatment had been at first acetate of ammonia mixture, then carbonate of ammonia, and later the addition of brandy. The hot-air bath produced some alleviation of the symptoms, and the consequent diaphoresis reduced the temperature.

Autopsy, twenty-two hours after death.—There were a few patches of recent lymph in each pleura, and a small quantity of serum. The lungs were congested, chiefly at bases, but there was no pneumonia. The bronchial tubes contained much mucus, and the lining membrane was highly injected. The pericardium was distended with turbid serum, and its surfaces were completely coated with a thick deposit of lymph. The muscular tissue of the heart and valves was normal. The other organs were quite healthy, and the body was well nourished.

The limb was examined, and the periosteum was found to be stripped completely from the lower third of the shaft of the femur by a thin layer of bloody serum containing a slight admixture of pus. The periosteum of the upper half of the tibia was similarly detached. The knee-joint was not implicated.

WEST LONDON HOSPITAL.

TWO CASES OF RETENTION OF URINE FROM LACERATION OF THE URETHRA; CATHETERISM; GOOD RESULTS.

(Under the care of Mr. Teevan.)

Charles O'H——, aged seven, was admitted into the hospital on the night of June 18th, suffering from retention of urine. Whilst the lad was riding on the back of a cart he fell off, about 4 p.m., became engaged in an altercation with the driver, and was knocked down and run over. Some blood escaped from the boy's penis, and he was afterwards unable to make water. When the patient was seen by Mr. Teevan the bladder was greatly distended, there were a few bruises on the right hip, and some blood-stains on the shirt. Mr. Teevan tried to introduce a small olivary elastic catheter, but failed. He then took No. 11 (French gauge) metal catheter, and by keeping the instrument well pressed against the roof of the urethra, and tilting up the point with the left forefinger in the rectum, succeeded in passing it into the bladder. When all the urine had flown out he cut off three inches of the shaft of the catheter, and tied the instrument in. Some ecchymosis appeared in the perineum on June 21st, and on the following day Mr. Alderton, the house-surgeon, withdrew the catheter, which had been borne very comfortably. On June 27th and 30th No. 11 metal catheter was passed, and again on July 3rd, on which day all ecchymosis had disappeared from the perineum. On July 7th, 12th, and 14th No. 15 metal was introduced, and on July 15th the boy was discharged quite well, passing a good stream of urine. Mr. Teevan, on July 17th, introduced No. 15 for the first time without the aid of the finger in the rectum. Soft catheters failed every time they were tried.

Case 2.—Thomas W——, aged thirty, a boot-clicker, was admitted into the hospital on June 20th, suffering from retention of urine. At 11 p.m. the previous night he was kicked in play in the perineum by a comrade who had only his stockings on his feet. The patient experienced much pain at the time, lost about half a pint of blood from the urethra, and was not able afterwards to make water. At 3 p.m. Mr. Teevan took a No. 15 olivary elastic catheter, passed it into the bladder with ease, and drew off a large quantity of urine, but did not leave it in, as the man could not enter the hospital till night. At 7 p.m. the patient was admitted. There was much blood on his shirt, and considerable fulness in the perineum, which was painful when pressed. At 11 p.m. the house-surgeon, Mr. Alderton, tried to pass a metal catheter, as the patient wanted to be relieved, but the instrument would not go. He then took a No. 11 (French gauge) olivary elastic catheter, and, having passed it with ease into the bladder, he drew off the urine and tied the instrument in. The catheter was retained for forty-eight hours, and after its withdrawal the patient had no further attack of retention. On July 1st Mr. Alderton passed No. 15 elastic catheter, and on July 3rd No. 16 was introduced by Mr. Teevan, and on July 7th and 10th No. 17 by Mr. Alderton. On July 12th Mr. Teevan passed No. 18, and the patient left the hospital the following day quite well, and able to pass a good stream of urine, which he had been unable to do for some years, as he had suffered much from stricture. On July 17th the man came to the hospital, when he was instructed in catheterism, and was enabled to introduce No. 18 soft catheter with ease for himself, and without drawing a drop of blood.

Mr. Teevan remarked that there were several points of interest in the above cases. Both patients had met with similar accidents. How was it, then, that metal instruments only could be passed in one instance, whilst in the other elastic catheters only could be introduced? These very facts established the diagnosis of the seat and particular form of laceration that had occurred in each case. M. Auguste Mercier had laid it down that if a laceration or false passage existed in the floor of the deep portion of the urethra, a curved metal catheter ought to be passed, as it could be made to hug the roof of the urethra, and so avoid slipping into the cul de sac in the floor. If, on the contrary, the laceration were in the roof, a straight elastic catheter ought to be introduced, as it always tended, when passed, to keep to the floor of the urethra, and would thus escape becoming locked in any rent in the roof of the canal. Inasmuch as in the case of the boy a metal catheter only could be introduced, it proved that the urethra had been torn in its floor, whilst the fact of an elastic catheter only being able to be passed in the man showed that the urethra had been torn in the roof. But how was it that the roof of the man's urethra had given way rather than the floor, which was the spot where the violence was applied? In all probability the following was the explanation. For some time the man had suffered from stricture in the deep portion of the urethra. Now, as a rule, in that complaint the floor was far more affected than the roof—i.e., the former was much thicker and stronger than the latter; hence, therefore, when the man was struck in the perineum, the weakest portion of the urethra, which was the roof, gave way rather than the floor, which was much stronger. The cases showed that soft and metal catheters had each their spheres of action, though, as a rule, if the urethra were completely torn across, a small olivary catheter would be found more likely than any other instrument to pick up the distal end of the divided canal. The treatment of a lacerated urethra was similar to that of a fractured bone. In each instance a splint was required to keep the ends of the thing torn in apposition, and in the instance of a lacerated urethra, the catheter acted as a splint. The retention of a metal catheter was always objectionable, as it tended to produce ulceration at some spot or other. Hence the less of the instrument that actually projected in the bladder the less chance would there be of cystitis. In order to carry out this object, several inches of the metal introduced in the boy's case had been cut off, leaving no more than was actually necessary to project in the bladder.

SOUTH LONDON OPHTHALMIC HOSPITAL.

TWO UNUSUAL CASES OF INJURIES TO THE EYE.

(Under the care of Mr. Edward Nettleship.)

Case 1. *Severe blow on the eye, followed by lasting damage to sight, without visible changes in any part.*—George S——, aged thirty-seven, a boiler-maker, received a blow from a lump of iron, which broke from some machine he was working at and struck his left eye; the blow was a forcible one, and knocked him down. Within two or three hours of the accident he went to a medical man and had a "drop" put into the eye, and very shortly after this the pupil was observed to be enlarged. No enlargement had been noticed before the drop was put in. He used the drops at home for several days, and attended the hospital for the first time ten days after the accident. He stated that the eye was "very bloodshot" for a few days, but that there was no swelling of the lids nor any prominence of the eye; indeed, the eye "seemed to be further in than the other, if anything."

On admission (Jan. 9th, 1875), the left pupil was partly dilated, and vision so defective in this eye that he could not see 200 Snellen at 20 ft. With a convex lens, 18 in., vision was raised from $\frac{20}{0}$ to $\frac{20}{40}$; and with + 6 he could see 2 Jaeger. With the right he saw $\frac{20}{30}$ unaided. The fundus of the left (injured) eye was healthy; and there was no trace of ecchymosis or other sign of injury about the eye or eyelid. He believed that the left had been as good as the right till the injury, but could not feel certain of ever having tried the eyes separately to test their sight until after the accident. He was an intelligent man. No treatment ordered.

Jan. 16th.—Vision of left = $\frac{15}{70}$; with convex 18 = $\frac{15}{40}$, very badly. Pupil still partly dilated. Right = $\frac{15}{30}$.

23rd.—Left pupil still slightly larger than normal. Without glasses with right he read 6 Jaeger; with left, 16 Jaeger.

The defect in the right (uninjured) eye depended on hypermetropia only, and he was directed to use + 20 spectacles.

On Feb. 27th sight of left eye still 16 Jaeger. Iodide of potassium in five-grain doses, with ammonia, was ordered thrice daily.

The sight was tried several times between the above date and April 24th, when it was found to be the same. Vision (without glasses): Right = 8 Jaeger; left = 16 Jaeger. At this date the left eye was again carefully examined with the ophthalmoscope after the use of atropine (the pupil having for long regained its ordinary size). No alteration of any kind was found in the fundus; the yellow spot region appeared healthy in the erect image.

Inquiries had been previously made as to syphilis, and his eldest child had been seen; there was no reason to think that he had ever had the disease.

The iodide was now omitted, and tincture of nux vomica prescribed in ten-minim doses, and continued regularly till June 19th, when treatment was discontinued.

On July 10th his sight and refraction were again tried with the following result:—Vision: Right = $\frac{20}{30}$ and 6 Jaeger (without glass); + 20 = $\frac{20}{20}$ perfectly; + 12 = 1 Jaeger. Left – $\frac{20}{50}$ and 16 Jaeger (without glass); + 30 = $\frac{20}{40}$; + 12 = 6 Jaeger badly, sight for near objects not being further improved by glasses higher than + 12.

As astigmatism was suspected, the patient was now directed to use atropine freely to the defective eye for several days, in order to try the refraction once more with accommodation fully paralysed.

On July 24th, the left eye being fully under the influence of atropine, its refraction was again tested, and $\frac{1}{12}$ of hypermetropia was found. With convex 12 sees $\frac{20}{40}$ partly. No astigmatism.

A final and very careful ophthalmoscopic examination was made at the same time, and nothing whatever abnormal was found in the eye. The media were clear and the fundus healthy. The details of the yellow spot region could be well seen by the direct method, and showed nothing unnatural.

Thus it appears that permanent defect of sight has been caused in this eye by the blow, unless we assume that the defect was present before. This fallacy, although it cannot be absolutely set aside by any conclusive statement on the patient's part, is almost negatived by the impossibility of assigning any cause for such previous defect. There was no old corneal opacity, and although both eyes were hypermetropic, there was no squint. It is true that the degree of manifest hypermetropia was not identical in the two eyes, but the degree was lowest in the bad eye, which does not agree with the hypothesis of an original difference of refraction between the two eyes having given rise to suppression of one image and consequent defect of the more hypermetropic eye. Moreover, the lens chosen for near objects was the same for each eye.

It may be suggested as not improbable that the blow caused hæmorrhage into the retina, or beneath it, and that a certain amount of disorganisation of its structure was thus caused, although the blood was afterwards completely absorbed. If this had occurred, however, it would seem unlikely that all traces of the blood should have been removed so soon as ten days after the accident, when the first ophthalmoscopic examination was made. Dr. Berlin, who has lately written on the subject,* considers the defect of sight in many such cases to depend on "transitory irregular astigmatism," due to changes in the lens. He describes haziness of a considerable area of the retina, sometimes with hæmorrhages, as the immediate result of the blow, and states that these changes disappear in as short a time as two or three days, but that some defect of sight remains after the ophthalmoscopic changes have vanished. If we accept this view a sufficient explanation is furnished of the condition of the fundus in the above case ten days after the blow.

Case 2. *Perforating wound of eye implicating the vitreous, but the lens escaping; simulation of an intraocular tumour.*—Mary R——, aged ten, was unpicking a laced boot with a fork when the prong slipped, jerked up, and wounded the left eye. She was taken to the hospital two days afterwards (July 4th, 1874), when Mr. M'Hardy found a perforating wound of the cornea with hypopyon; the treatment was atropine and a compress. The hypopyon was absorbed, but in other respects the eye did not improve. On the 23rd she was seen, in Mr. Nettleship's absence, by Mr. Carter, who found that a whitish reflex was thrown from behind the transparent lens simulating a gliomatous growth, but that the tension was diminished. He advised immediate excision. Mr. Nettleship saw the child for the first time on the 25th, and noted in substance as follows:—"Left eye: No perception of light; tension diminished; general congestion of sclerotic; eye not tender; no anterior chamber; a radial linear mark to inner side of centre of cornea, to which the iris adheres near its circumference; pupil slightly displaced, but nearly round; lens transparent, but shows a slight mark on centre of anterior surface; a whitish reflex, easily seen in daylight, from the back of the eye; by focal illumination it is seen that towards the circumference the white gives place rather suddenly to red colour, which is most abundant on the inner side of the eye (corresponding to the position of the wound)." An opinion was expressed that the substance behind the lens would probably prove to be lymph and blood in the vitreous, the result of a perforating wound passing close to the edge of the lens without wounding it, rather than a malignant growth. The eyeball was removed by Mr. Nettleship the same day, and, on dissection, a mass of yellow lymph was found behind the lens, quite covering its posterior surface, and lining the entire surface of the ciliary body. The retina was everywhere *in situ*, and, with the exception of slight milkiness, appeared healthy to the unaided eye.

NORTH RIDING INFIRMARY, MIDDLESBOROUGH.

CASE OF STRANGULATED INGUINAL HERNIA; ASPIRATION; RECOVERY.

(Under the care of Mr. Geo. Longbotham.)

For the following notes we are indebted to Mr. W. Stirling Anderson, house-surgeon.

R. W——, aged twenty-eight, was admitted on May 5th, 1875, suffering from symptoms of strangulated hernia. On the evening of the 4th he was engaged in his usual occupation, that of a labourer at a blast furnace, and about 8 o'clock strained himself severely when lifting some heavy weights. He continued to work on, without any pain or uneasiness, till 9 o'clock, at which hour his shift went off duty, but shortly after ceasing labour he experienced cramps in the belly. On looking at himself he found a swelling in his scrotum. He was visited at his home by a surgeon, to whom he did not say a word about the scrotal swelling, as there were several people in the room. After midnight he began to complain of very great pain in the swelling and lower part of the belly, vomiting setting in about the same time. The vomiting proving persistent, the medical attendant was sent for, and he endeavoured to reduce the swelling by taxis, but without avail. In the morning, about 8 o'clock, he was put under chloroform and the taxis again employed, but with no better effect. He was admitted into the hospital at 11 A.M.

---

* Zehender's Klin. Monatsbl., 1873; abstract in Ophth. Hosp. Reps., vol. viii., p. 105.

On examination, a large inguinal hernia was found to occupy the left scrotal region. The tumour was very tense and red, showing at its neck a very decided constriction, just at the seat of the external ring. The patient having been put under chloroform, taxis was once more resorted to to effect reduction, but, proving futile, was not persevered in, as the state of the parts did not warrant this. The No. 2 needle of a pneumatic aspirator was introduced into the tumour, and four ounces of darkish serous fluid withdrawn. Mr. Longbotham then passed his forefinger up behind the cord so as to dilate the external ring with the canal above, and gently employing the taxis had the satisfaction to feel the tumour yield, and disappear within the abdominal cavity. A pad was adjusted, and one drachm of the solution of hydrochlorate of morphia was given.—Same day, 9.30 P.M.: Perfectly quiet; no pain complained of; he only has some uneasiness in inguinal canal on turning. Slops ordered. Temperature 98·4°; pulse 64.

May 6th.—Morning: Patient feels quite well this morning. Temperature 98·8°; pulse 64.—9.30 P.M.: Temperature 98·6°; pulse 76.

7th.—1 P.M.: Is quite well, and complains merely of being kept in bed. Temperature 98·4°; pulse 60.

Progress continued in the same satisfactory way, and on the morning of the 11th he had a spontaneous motion of his bowels. They were moved on the following day, also on the 13th, on which day he was discharged. At this time there was no tendency to recurrence of tumour even on coughing.

Reviews and Notices of Books.

A Manual of Histology. By Prof. S. STRICKER. American Translation. Edited by ALBERT H. BUCK, Assistant Aural Surgeon to the New York Eye and Ear Infirmary. New York: W. Wood and Co. London: Trübner and Co. 1872.

STRICKER'S Manual of Histology has taken such an established position as the text-book on this subject, and has become so well known in England through the excellent translation of Mr. Henry Power, published by the New Sydenham Society, that it may seem almost superfluous to call attention to an American edition published so long ago as 1872. But although well known in America, we understand that the work has been only recently introduced into England, and it deserves notice on other grounds.

The first part of this edition is simply a reprint of Mr. Power's translation, constituting the first volume of the edition of the Sydenham Society. The remainder of the work has been retranslated by Mr. Buck and his American coadjutors. Mr. Buck's work includes the articles on the liver, the larynx and trachea, the lungs, kidneys, supra-renal capsules, ovary, serous membranes, organs of taste, and the development of the simple tissues. The articles on the urinary bladder and testicle are translated by Ed. L. Keyes; those on the mammary gland, male and female external genital organs, and uterus, and on the membranous labyrinth and the synovial membranes by Thomas E. Salterthwaite; the organ of vision by Henry C. Ens; and the other minor articles have been entrusted to Drs. F. Delafield, Lucius D. Bulkley, and J. Orme Green. Of the articles on the nervous system those on the spinal cord and sympathetic nervous system were undertaken by Dr. Edward C. Seguin, whilst to Dr. James J. Putnam fell the lot of translating Meynert's article on the brain of mammals.

The translations are for the most part exceedingly good and clear, and whilst adhering to the original text, they are free from German idioms and are neither laboured nor obscure. The advantage of the plan of entrusting the translations of articles to gentlemen specially acquainted with subjects treated of is very apparent, enabling the translator to give the equivalent terms commonly in use, a great gain when we consider how much words tend to become specialised in their application. In some cases a desire for exactness has led to a translation of the *ipsissima verba* used in the German, instead of the substitution of the English equivalent; thus we find the *fenestrum ovale* called the "oval window," a translation which, though graphic, seems scarcely less advisable than that of the *foramen rotundum* as the "round hole." A similar inacuracy is found at the heading of each article, where the abode of the author is designated by "*in*" instead of "*at*"—thus "Th. W. Engelmann, *in* Utrecht," which is German, not English.

We naturally turned to Meynert's article on the Brain of Mammals as a crucial test of the value of the translation, but here we found that the American editor had been at a great advantage as compared with the English. The translation was entrusted, at Prof. Meynert's special request, to Dr. J. F. Putnam, who was at the time a pupil in Meynert's laboratory, and well acquainted with his researches, and in all doubtful points referred to the author for information. Bearing in mind the difficulty experienced by Mr. Power, aided by Drs. Payne and Broadbent, in translating or even understanding some portions of this obscure article, and the dictum of a German physiologist, that "es muss erst Deutsches gemacht werden," we were prepared for a similar experience in the American translation; but we are not surprised to find that Dr. Putnam found it desirable to act the part of an interpreter rather than merely that of a translator. It would, indeed, have been impossible to do otherwise, if the author's views were to be represented, and Prof. Meynert may be congratulated on having found so able an exposition of his researches, such as could only have been undertaken by someone thoroughly acquainted with his preparations. Otherwise there was some danger lest his observations should share the fate of Jean Paul Richter's philosophy, whose author, when asked its meaning, said (to quote Hans Breitmann), "Gott im Himmel only weiss, for I have quite forgot." It is satisfactory to have such a guarantee that Dr. Putnam's translation really gives Meynert's views, for we frequently find that a single word, apparently with little meaning, and which has been considered as such by the former translators, is expanded into a long explanatory sentence by Dr. Putnam, with the effect of completely changing the meaning of the whole context. The result is that Dr. Putnam's translation, whilst more connected and intelligible, is much longer than that of the Sydenham Society. We give a passage taken at random from the two translations, of which Mr. Power's may be taken to be an accurate translation of the original:—

SYD. SOC. TRANS.	DR. PUTNAM.
The tegmental origin of the antero-lateral column permits distinct areas to be distinguished in two different directions; first, those placed one behind the other, which, proceeding from the grey floor, are (1) the *posterior longitudinal fasciculi*; (2) the (middle) motor area; (3) the fillet (*Schleifenschichte*, Reichert); and, secondly, those in lateral juxtaposition, which are (1) the region of the *anterior column*, forming the territory adjacent to the raphé that is bounded laterally in the pons by the roots	Thus constituted, the surface obtained by cross section of the collective groups of fibres conveyed by the tegmentum to the antero-lateral spinal column may be divided, for purpose of description, into different districts, as follows. Proceeding forwards from the grey floor of the fourth ventricle, three such districts, lying *one behind the other*, may be distinguished. The first contains the *posterior longitudinal fasciculus*; the second, the (middle) *motor region*; the third, the *stratum lemnisci* (Reichert). Again, in proceeding from the median line outwards, there may be distinguished two such districts lying

of the nervus abducens, and in the oblongata by the roots of the hypoglossus; and (2) the region of the lateral column, extending from the boundary as far as to the ascending roots of the fifth, in which also the *pes* of the *fillet* is enclosed. (*Fuss de Schleife*, Stilling.)	*side by side*, the first being occupied by the groups of fibres destined to form the anterior spinal column, a region which borders on the median raphé, and is bounded outwardly, in the pons, by the roots of the nervus abducens; the second by the group of fibres destined for the *lateral column*. The latter district borders on the former, and extends outwards as far as the ascending roof of the fifth pair, enclosing therefore the *pes lemnisci*. (Stilling.)

It is obvious that Dr. Putnam's translation should rather be called a paraphrase or exegesis, and it might well be retranslated into German to replace the original article.

Of the general get-up of the work we cannot speak too highly; the type is clear, and there are few press errors, and the illustrations throughout are especially well engraved. The only objection is the unwieldy size of the book, which is complete in one volume, and can therefore hardly be called a "handbook" as regards its portability.

An Introduction to Pathology and Morbid Anatomy. By T. Henry Green, M.D. Lond. Third Edition. pp. 424. London: Renshaw. 1875.

The author of this valuable little work is to be congratulated on the demand for it that has already called forth a third edition. It affords gratifying testimony to its value and popularity as a text-book. It possesses, further, all those qualities which render such a book popular among students. It is written in clear and concise language; it is confined almost entirely to statements of fact, theoretical views being for the most part kept out of sight, and it is, above all, fully and exceedingly well illustrated. The number of illustrations, indeed, has increased rapidly with each addition, and we perceive in the present edition that several woodcuts have been replaced by new and original drawings. The author has also bestowed a careful revision on the text, adding such new matter as was necessary to keep the work up to a level with modern pathological research, rearranging and rewriting some chapters. Among other new matter we notice a chapter on tissue-changes in pyrexia; a brief account of pulmonary emphysema under the head of atrophy; the pathology of "surgical kidney," &c. Some additions have also been made to that valuable chapter of practical remarks on the preparation and mounting of specimens, which was first introduced into the second edition.

The Monthly Microscopical Journal. August 1st, 1875. No. LXXX.

This number contains several articles of unusual interest. Dr. Braithwaite continues his account of the Bog-mosses (sphagna), with details of the Sphagnum portoriceuse and Sphagnum macrophyllum. The Rev. D. Edwardes, after alluding to the various units of linear measurement that have been proposed, as the quadrant of the meridian, the length of a pendulum vibrating seconds, the diameter of a sphere of the same volume as the earth, and pointing out the objections to all, suggests that the wave length of orange light in vacuo, which would give 1,500,000 wave lengths in one yard, would prove an excellent standard. What do the physicists say to it? To this succeeds a short and rather amusing paper on the Microscope and its Misinterpretations, by John Michels, chiefly bearing on the differing descriptions that have been given of the Podura scale. Dr. Beatty describes a mode of double staining wood and other microscopical sections, founded on the fact that benzole fixes the aniline colours. Dr. Martyn has a good paper on Conjoined Epithelium, particularly referring to the "prickhand ribbed" cells of German writers. Dr. Bastian's address delivered before the Pathological Society of London on the Microscopic Germ Theory of Disease is reprinted *in extenso*. Dr. Fleming describes a modification of Rutherford's freezing microtome. Lastly, Dr. Lionel Beale has a paper on the Origin of Life.

IMPERFECT MEDICAL QUALIFICATION.

Some years ago it was pointed out by a contemporary that a large proportion of the practitioners of the country whose names were on the Medical Register were possessed of only one qualification. It is very unsatisfactory to have to report that the same state of matters seems to continue. In accordance with the standing orders of the General Medical Council, the Registrar has recently issued the list of those gentlemen who have registered in the first six months of the year, giving the nature and date of their qualifications, and the date of their registration. The list of new registrations is very large—namely, 419. This number is much in excess of that in any corresponding period, and shows that if there is not an increasing number of practitioners, there is at least an increasing conviction of the advantages of being registered. Clearly, for legal purposes, a man can scarcely be said to have qualifications until they are registered. The fees accruing to the Council for this batch of registrations will amount to the sum of £2095. But in our opinion the most interesting point in this list is the large proportion of gentlemen who have but one qualification to register. Thus, out of a total of 419 registrations, 164 are registered with *one* qualification only—viz., Member Royal College of Surgeons of England, 101; Licentiate of the Society of Apothecaries, London, 25; Lic. Royal Coll. Phys., Edin., 3; Lic. Royal Coll. Surg., Edin., 10; Lic. Fac. Phys. Sur., Glas., 8; Univ. of Glas., 3; Lic. Royal Coll. Sur., Irel., 6; Apothecaries' Hall of Dublin, 4; University of Dublin, 1; Queen's University in Ireland, 3. From this it appears that two-fifths of those newly registered are unqualified in regard to one branch of the profession. The single qualification is in the large majority of cases a surgical qualification. Thus of the 164 single qualifications 125 were surgical, as against 39 medical. The bulk of medical practice is made up of medical cases, for attendance on which gentlemen with surgical qualifications are not enabled to recover. If any facts could give the death blow to the present system of licensing practitioners, or a stimulus to the movement for a one-portal system, it would be such facts as those we now publish.

THE WINTER SESSION AT THE LONDON MEDICAL SCHOOLS.

The metropolitan medical schools will open on the 1st of October, with the exception of Westminster Hospital and University College, at which institutions the session commences on the 4th of the month. The usual introductory addresses will be delivered as follows:—At St. Mary's by Dr. John Randall, at St. Thomas's by Dr. Payne, at the Westminster by Mr. Davy, at St. George's by Dr. Robert Barnes, at the London by Dr. Bathurst Woodman, at the Charing-cross by Mr. Fairlie Clarke, at King's College by Professor Curnow, at University College by Professor Corfield, at the Middlesex by Mr. Thompson Lowne, and at Guy's by Dr. Stevenson.

As is well known, the custom of delivering an introductory address at St. Bartholomew's Hospital has been discontinued for some years. The London School of Dental Surgery will commence its session on October 4th by the distribution of prizes, on which occasion Sir James Paget is expected to attend.

THE LANCET.

LONDON: SATURDAY, AUGUST 21, 1875.

ALTHOUGH opinions were at first greatly divided as to the significance and importance of the recent meeting of the British Medical Association at Edinburgh, the final decision seems to be that as far as the business of the sections and the general arrangements at Edinburgh itself were concerned matters were well enough, but as far as concerned the management of the general business of the Association there was great room for improvement. Whatever was good and commendable has been already sufficiently dwelt on in our columns and elsewhere, so that it may not be uninteresting or unprofitable to take a different view, and to consider some of the lessons which the experience of the meetings affords.

In the first place, the election of Sir ROBERT CHRISTISON to the presidential chair was a happy circumstance, and went far to allay suspicion and to appease many of those who had felt aggrieved at the manner in which they had been treated by the Committee of the Council. To those, indeed, who did not know that some members of the professorial staff of the University had at one time positively declined to take part in the business of the Association, on the ground that great want of respect had been shown to certain of their colleagues, no sign of resentment or of want of sympathy was apparent, even at the first general meeting. Everything calculated to give at least an outward appearance of unanimity seemed to have been arranged, and very efficient means had been taken to avoid the possibility of a discussion. Few persons, for instance, knew why the Professor of Medicine in the University of Edinburgh was not present at any of the meetings of the Association, and fewer still could conjecture why the presidency of the Medicine Section was given to a London physician who is not attached to a tutorial hospital.

Evidence was not, however, long wanting that the Council of the Association regard themselves as irresponsible representatives of the Association. At the conclusion of Sir ROBERT CHRISTISON's long but in many respects excellent address—which we shall notice on a future occasion—the first general meeting was held. As we have already announced, at this meeting, which probably did not comprise more than fifty members beyond those who were also members of the Council, the most important business of the whole year was transacted in a manner altogether extraordinary. Instead of adjourning the meeting till some time when they could be certain of a full attendance, the Council, contrary to the wishes of those present not of their own body, actually voted for the adoption of their own report, unread. So harmoniously did they work together that, by the aid of a few votes from the non-official members, they were able to override the thirty-one independent members, who desired that the report be either read at once or printed for circulation among the members, and discussed next day or at any other more convenient time. Such a proceeding as that we have referred to may have been legal, but can scarcely be said to be exactly constitutional. The Council are the responsible representatives of the Association, but their responsibility is certainly nullified or reduced to a minimum if they have the power to vote for the adoption of their own report, and by that means to contravene, as they may do in the small meeting, the wishes and desires of the members of the Association. If such an undesirable course were again adopted, it would not be surprising to find the members determined to undertake the election of members of the Council, which seems at present to be self-elective, and in future to keep a very strict watch on their proceedings.

Scarcely less remarkable than the adoption of the report of the Council, unread, was the adoption, under identical conditions, of the remodelled bye-laws of the Association. It was urged by Dr. SIBSON that the bye-laws had been carefully considered by the Committee; so that, although there was much that was undesirable, and even objectionable, he begged that those present would waive all discussion and accept *en bloc* the bye-laws of which, under the circumstances, they knew nothing. When, however, a protest was made that a similar argument had been made use of to avoid discussion of the altered bye-laws at the private meeting of the Council in the morning, Dr. SIBSON admitted that, although he wished to avoid any discussion of the bye-laws at that meeting, there were some things that would require alteration, and that some part of what had been done would before long have to be undone. There would, he pointed out, be plenty of opportunities to discuss the bye-laws next year, and it was competent to anyone, by giving due notice, to propose the alteration of the existing bye-laws. After this procedure had received the strong recommendation of Mr. HUSBAND, of York, and Dr. CARPENTER, of Croydon, it was finally accepted by the members, notwithstanding the vigorous and manly protest of Dr. CHADWICK.

Another incident occurred at the first general meeting which must be mentioned here, as it affords a good illustration of the manner in which the Council does its work. Before the report was adopted, Mr. O. PEMBERTON, of Birmingham, stated that he was desirous of calling the attention of the members to the fact that on the list of names of those who were going to read papers there were the names of two ladies, who, he presumed, were members of the Association. Dr. SIBSON and Mr. HUSBAND observed that, as there was nothing about the admission of lady members in the report, the question could not at that time properly be discussed. Mr. PEMBERTON replied that he would read the terms of the motion he intended to make, and then it would be seen whether he was out of order. The motion was as follows:—"That it be an instruction to the secretary, between now and the next annual meeting, to issue a circular addressed to every member of the Association, requesting an opinion 'Yes' or 'No' as to the admission of female practitioners to membership." The President at once stated that he should not allow the subject to be moved. The matter then dropped; there was, however, a tacit but distinct understanding that Mr.

PEMBERTON'S motion should be brought forward at the next general meeting. Accordingly, next morning Dr. FALCONER, who occupied the chair for a few moments in the absence of Sir ROBERT CHRISTISON, promised Mr. PEMBERTON that he should have an opportunity of bringing his motion forward as soon as the business on the Agenda paper had been transacted. In due time Mr. PEMBERTON rose, and, in proposing the motion of which he had given notice, said that he did not know how the ladies referred to had been made members of the Association—whether by a vote of the Committee of Council or by the vote of any branch; but he thought that on such a question the sense of the Association should have been previously taken. Without saying whether the matter commended itself to his judgment or not, he pointed out that the rules of the Association speak of the members invariably as of the male sex. Dr. MARSHALL, of Clifton, in seconding the motion, reminded the members that they have, or at least should have, some control over the management of the business of the Association, and that they should be prepared at the annual meetings to devote some time to the transaction of business, as well as to mere complimentary speeches. He astonished not a little the majority of those present at the second general meeting by informing them that during their absence on the previous evening the report, which few had read or knew anything about, had been passed. The members were, he alleged, too willing to leave their affairs to be conducted by the Committee of Council; and the admission of ladies to the membership of the Association unknown to the members generally was, he hinted, sufficient proof that some kind of control or check should be kept on the action of the Council. By whatever means the ladies had been appointed, a great liberty had been taken with the rules of the Association. An innovation so important should not have been made without first ascertaining the feeling of the entire Association. After Dr. A. P. STEWART, a member of the Council, had informed the audience that it was he who had had the pleasure of proposing Mrs. GARRETT-ANDERSON, one of the ladies referred to, and that that lady had been duly elected by the Metropolitan Counties Branch, Dr. CARPENTER, of Croydon, who on the previous evening had advocated the adoption without discussion of the altered bye-laws, submitted that, according to those very bye-laws, Mr. PEMBERTON must give at least seven days' notice of his motion, and he even went so far as to move that Mr. PEMBERTON be requested to give due notice of his motion. This amendment, which necessarily precluded the consideration at that meeting of the admission of ladies to membership, was seconded by Mr. E. HART, who spoke of the disabilities that the members would impose upon themselves by adopting Mr. PEMBERTON'S resolution, as they would require the sanction of the President of the Board of Trade to empower them to reject ladies. Fortunately, however, the attendance of the members at this meeting was large, and questions could not be disposed of as they had been the previous evening. The audience showed most unmistakably that they had formed very strong opinions on the matter,—that, as the Council had practised one irregularity, they would make another, and for once override their bye-laws. When Sir R. CHRISTISON observed that Mr. PEMBERTON'S motion was in order, and Dr. STEELE had remarked that the Association could surely give instructions to its secretary without seven days' notice of the motion, Mr. HART withdrew the seconding of the amendment. The result was that, when Mr. PEMBERTON'S motion was put to the meeting, it was carried with only one dissentient.

The business at the other general meetings was all of less interesting character, and did not call forth much discussion. Dr. BEGBIE'S address has already been noticed, and in another column will be found some remarks on Professor RUTHERFORD'S Address in Physiology. It remains, therefore, to consider briefly Mr. SPENCE'S excellent address. Here let us say that if Mr. SPENCE had previously consulted the wishes of the majority of the members of the Association he could not have succeeded better in meeting their views. Large numbers of persons had attended Mr. LISTER'S demonstrations on antiseptic surgery, and there was a widely expressed desire to hear something on the other side, and it was felt that the most competent person to offer an opinion would be someone connected with the Edinburgh Infirmary who did not practise antiseptic surgery. Mr. SPENCE'S address was therefore gladly received. We need only refer to the abstract of Mr. SPENCE'S address that we published last week to show what is the opinion of the Professor of Surgery at the Edinburgh University of the value and importance of antiseptic dressings.

It will be seen that we have in our remarks dwelt more on the political than on the professional aspect of the British Medical Association. We have, in no captious spirit, pointed out a few failings and shortcomings which everyone who has the welfare and prosperity of the Association really at heart must desire to have put right. Under proper management the British Medical Association is capable of becoming a great power for the political and social advancement of the profession; and if the governing authorities can succeed in convincing their constituents that they seek only to carry out the wishes of the entire Association, these annual meetings will become valuable means of promoting the union and good fellowship that should exist among the members of an honourable profession like that of medicine.

* * *

ALTHOUGH much has been written concerning the symptomatic phenomena of heatstroke—better known under its less appropriate and more limited name of "sunstroke,"—yet but little advance has been made with regard to the pathological changes at the root of the affection. This is, doubtless, in great measure owing to the frequently sudden fatality of the worst cases, and their occurrence under conditions which render careful and accurate post-mortem investigation impossible. Yet hardly a summer passes—if not in this country, at least on the Continent, and far more in the United States and the tropics—without some cases of this nature occurring. We propose, therefore, to direct attention to the most recent attempt to explain the symptomatology by a rational interpretation of the changes detected after death, which has been made by Professor ARNDT, of Greifswald, in VIRCHOW'S *Archiv* (vol. lxiv., p. 15). Although much of his argument is based upon assumptions and not upon actual histological proof, yet, taken as a whole, it cannot but be considered as of certain value, and worthy of passing notice.

The groundwork of Professor ARNDT's contribution is but small—viz., the records of three autopsies made in the year 1870 upon fatal cases that occurred in the 3rd Army Corps of the German Army then stationed at Berlin. The literature of this subject is full of the records of cases occurring in military life, where the too rigid adhesion to unsuitable modes of clothing and discipline has lain at the root of the mischief. Of this our own Indian Army affords many sad examples. In the present case three divisions of the corps mentioned marched out on exercise (*Uebungsmarsch*) from headquarters at the end of July, 1870. The march lasted about five hours, inclusive of two halts; but the day was sultry in the extreme, and the route lay through the arid sandy plains surrounding the German metropolis. The troops were insufficiently supplied with water; and in spite of the relaxation from heavy marching order which was permitted as soon as a few men showed signs of distress, many succumbed to the effects of the heat before the day's march was over. Of the number attacked (it is not stated how many) seven died; and of these, as above mentioned, three supplied Dr. ARNDT with the material of his research. The most striking pathological changes were fluidity of the blood and engorgement of all the larger systemic and pulmonary vessels, associated with marked anæmia of the parenchyma of the viscera—brain, liver, kidneys, &c. Thus side by side with engorgement of the coronary and cardiac vessels, and even subperi- and endo-cardial ecchymoses, the muscular tissue of the heart was pale and swollen. The brain was moist, its ventricles distended with fluid, convolutions flattened, and sulci obliterated; and yet withal the veins and sinuses of its membranes were full of blood. ARNDT remarks that this condition of brain has been erroneously described as hyperæmic, whereas the nervous substance was really in a high degree anæmic. The condition of the other viscera was similar. There was the same overfilling of the larger vessels of the liver and kidneys, while the parenchyma was pale, and the organs notably enlarged. The intestinal and vesical mucous membrane was equally pallid; but the condition of the mesenteric vessels was not noted. In the lungs only did the hyperæmia seem to prevail uniformly. Upon what did this "parenchymatous anæmia" depend? This question was readily answered as to the liver, kidneys, and muscle,—all of which presented the characters of the condition known as "cloudy swelling." The brain, however, presented rather the condition of œdema; but was it here even mere œdema? Dr. ARNDT thinks not; and judging from the analogy presented by the other viscera, he concludes that in the brain also there was a similar condition of "cloudy swelling" of the cellular elements—a condition which he believes to be of an inflammatory rather than of a degenerative nature.

Now this condition of muscles and viscera, it is well known, is found to its most marked extent in infectious diseases—as typhus, typhoid, variola, pyæmia, &c.; and in all such cases, be it observed, there are two factors at work—viz., an altered blood condition and high pyrexia. It is met with in its highest degree in those cases in which the second factor predominates, the changes being most marked in those patients who have succumbed at the height of the febrile process. Adverting then to the important place taken by rise in the temperature of the body in heatstroke, the writer gives full details of the affection in its different degrees of intensity. Even in the mildest cases—those most readily subdued by treatment—the temperature of the body may rise from 100° to 104° F. or more; this is accompanied by rise in the rate of the pulse and respiration, increase in secretion of sweat (and here he differs from other authorities, for he avers that only in the severest examples is the skin dry), thirst, muscæ volitantes, tinnitus aurium, oppression at the chest, &c. The transient nature of such cases and their ready relief are enough to show that grave organic mischief is not set up here. But in less favourable cases the temperature rises to 105° or 107°, the pulse to 140, and the respirations to 40, with aggravation of all the symptoms, together with headache, convulsions, and other nervous disturbances. From such an attack recovery is tedious, and permanent mental weakness may be left behind. Finally, in the worst cases of all (those which Dr. MOREHEAD has classed under the head of "cardiac" as distinguished from the "cerebro-spinal" form), the skin becomes very dry and pungently hot, the temperature may reach 111°, the pulsations of the heart are too rapid to count, its sounds are inaudible, and death may occur suddenly from syncope, or after a slight rally the patient may relapse and die comatose. In cases, then, either of the second or third degree, it is evident that organic changes have been set up, so that, even if recovery ensue, their effects are left behind.

Analysing these facts, ARNDT attempts to explain them from the morbid states found after death. The fluid dark blood has been found by OBERNEIER to be of acid reaction and to contain an excess of urea. Whether this acidity be due to an excess of carbonic or of lactic acid is a matter of question; but it is enough to know that here also, as in septic diseases, the blood is charged with noxious products. However, it is probable that here this is of minor importance to the rise in the temperature of the body, which is the initial fact, and one wholly in accordance with recent experimental research upon the effects of high temperature upon the bodily organism; for in these experiments the parenchymatous changes were such as described here—viz., "cloudy swelling"; and, with facts such as these, we are forced to admit that a high rate of temperature *is* a most grave factor in disease. In heatstroke, then, the rise in the bodily temperature is the primary act; it may lead to sudden death by setting up incipient myocarditis; or, if the patient survive a little, all the organs more or less bear evidence of a parenchymatous change, as shown by "cloudy swelling" of their elements—a process maintained by the morbid blood. On this hypothesis, too, in cases of recovery, may be explained the change that renders the brain a *locus minoris resistantiæ*, thus rendering the subject of sunstroke prone to the development of insanity, epilepsy, or other neurosis.

◆

IT would be comforting if it were possible to accept Mr. DISRAELI's definition of "Sanitary Reform." We refer to the interpretation of that not unfamiliar phrase offered by the Prime Minister in his "summing-up," at the Mansion

House, towards the close of a session which he was pleased to characterise as "crucial," and charged with the onerous duty of "redeeming your pledges." It is to be deprecated that any question or difference of opinion should arise as to the nature of those pledges. If one party to a contract claims, while the other declines, to hold it discharged, there is commonly an end of mutual confidence; and it cannot be denied that a contract having very direct relation to this question of sanitary reform was entered into between the Conservative party and the country when the former was raised to power. We should, therefore, be unfeignedly sorry to find that we had been misled by the glib use of a phrase which Mr. Disraeli somewhat tardily complains is "so little understood." Still we cannot forget that what the medical profession, and probably the public, understood by sanitary reform, was something incomparably better defined than "most of the civilising influences of humanity." Sanitary reform is undoubtedly one, perhaps not the least potent, of the civilising influences of humanity; but it does not follow that a Government, which in some vague sort of way strives to foster civilising influences, can claim credit for inaugurating an era of sanitary reform. Nevertheless, such an era we believe the country expected when, after having for five years strongly and studiously "impressed upon the public mind that sanitary reform was the great object and need of the day," the propounders of this gracious doctrine undertook to demonstrate their theory in practice. Looking to the sanitary reforms already effected, the real business can scarcely be said to have begun. It is, therefore, almost irritating to be told that the phrase upon which the whole undertaking hinges is "little understood"; that, in point of fact, it is susceptible of a more diffuse construction than simple folk supposed; and that instead of strong measures for the protection of the public health, a visitation of good intentions must be held to redeem the pledge and satisfy the contract.

A less discouraging view of the political situation seems impossible, because the session which has just closed is pointedly declared to have been "a crucial one," specially devoted to redeeming the pledges given by Ministers before taking office. The Cabinet reviews the labours of the last six months, expressly in this light, with complacency and even self-gratulation. This is not the time, nor are we disposed, to be unthankful for small mercies, provided always that they are not paraded as substitutes for the larger benefits we have a right to demand. We do not under-estimate the difficulties with which the Government has had to contend. We recognise and make full allowance for the general inertia produced by exhaustion. But looking at the results of a year's labour, not too critically, and frankly accepting them as the products of a sincere endeavour, it is impossible not to be disconcerted at the pitiful dimensions of the output, and still more seriously dismayed by the lack of stedfast purpose the work accomplished betrays. When we are asked to regard it as the redemption of a pledge to resolutely and effectually prosecute sanitary reform, the feeling of dissatisfaction changes to one of chagrin.

The session opened well. The Queen's speech gave prominence to Bills projected for the improvement of the dwellings of the working classes in large towns, for the consolidation and amendment of the Sanitary Laws, and for the prevention of the pollution of rivers. The business of the opening night was of happy augury. On the 13th of February we observed with satisfaction that "the President of the Local Government Board gave notice of his intention to introduce a Bill to repeal the Adulteration of Food Acts, and make better provision for the sale of food and drugs in a pure state. ...... Not less remarkable than the prominence thus assigned to sanitary measures in the work of the session was the tone in which these measures were referred to by various speakers in the House of Commons." We were prompted to say—"The sanitary measures proposed show that the Prime Minister is about to give effect in Parliament to those principles of social legislation which he announced from the hustings; and the masterly statement of Mr. Cross in introducing the first of the measures gives hope that the sanitary work of the Government will be conceived and furthered with due regard to its gravity and perplexity."

Hope told a flattering tale. The original conception was well enough. The preliminary sketches presented to Parliament and laid before the country, if not faultless, were fair; their colouring was firm, and even captivating. The severest, the most captious, critics acknowledged the skill of the artist. A feeling of calm and trustful contentment possessed the public mind. But when the time came to produce the finished pictures, wrought on the lines and in the spirit of the approved designs, some were too far from completion to be exhibited at all, or, on frivolous pretence of want of space—as in the case of the Rivers Pollution Bill,—were quickly lumbered out of sight; while others, what with lowering high lights, picking out shadows, blending half-tints, and generally scumbling over marked features and striking contrasts, had wholly lost their character and effect. Perhaps the most successful achievement was the consolidation of Sanitary Laws—the idea of *amendment* had practically dropped out,—but this was of the nature of a catalogue, rather than an original art work. We have given the Government full credit for their Artisans' Dwellings Act, and are prepared to cherish the most generous hope as to its success. For the rest, bold, terse Bills became attenuated and feeble Acts; prohibitory restrictions dwindled into permissions to refrain from wrong-doing, or at best facilities for doing right. In some instances, notoriously that of the Food and Drugs Bill, matters have been muddled instead of being mended. The strong arm of the law, which threatened to strike down and crush offences, was adroitly limited to showing its prowess by killing flies on the whole skins of offenders. Concession extracted the sting from compulsion; and Samson, shorn of his locks and with his eyes put out, was left leaning against the door-posts, ready to be crushed by the fall of the house he had promised to bring down on the heads of his enemies. All this may have been interesting and significant from a party-political point of view, but it was infinitely aggravating to the common sense and earnestness of an anxious people. The grievances of which the nation had long complained and for which it looked hopefully for redress, the evils under which it groaned and chafed, the perils by which its life was beset, were real, and would not admit of pleasant trifling. If, already, a feeling of fretful discontent has sprung up in the stead of placid expectancy, if peevish distrust has begun to take the place of respectful confidence, the Government has only itself to thank for the untoward change in public sentiment. Its misfortunes have been of its own making. It has suffered little from the wit and nothing from the energy of political opponents. Five years of unremitting endeavour to impress upon the public mind that sanitary reform is the great object and need of the day could not be without its effect. The disappointment occasioned by the discovery that a pledge to compass that object and satisfy that need is to be redeemed by performances little more than perfunctory must be proportioned to the depth of the impression of need and urgency intentionally produced.

It seems inexplicable that the Government should seriously elect to be judged by the session so strangely concluded. We can understand Ministers making the best of what they cannot amend; and if the attempt to place their achievements in the most favourable light, and to throw a veil over their failures, were undertaken in a spirit of modesty—if they pleaded obstacles to progress and prayed time for the fulfilment of their promises, the situation would engage sympathy, and might even command respect. But when they point triumphantly to the past as "crucial," when they claim the acknowledgment that they have redeemed their pledges, it is impossible to feel otherwise than disheartened and perplexed. The very ground of hopefulness is cut from under our feet. To tell a nation you know its objects better than it knows them itself, to expend time and argument in impressing it with the deepest and keenest sense of its needs, to hold out the most brilliant promises of redress—if you are entrusted with its confidence,—and when you grasp the reins of government to do next to nothing, and that little indifferently; then to turn round and protest you have redeemed your pledges, which were "little understood," is more likely to ruin the prospects of a Ministry, be it never so fair-spoken, than a world of mere stupidity or an age of simple inaction. Great expectations unrealised readily give rise to great revenges. To repeat the experiment of generous undertakings without a fixed determination to discharge the obligation in full and at all costs would be to dare the disgust as well as the disappointment of an indignant people. Nothing short of a complete and effectual remedy for the social and sanitary evils exposed will now suffice to allay the anxieties or quiet the importunities of a nation growing daily more intelligently solicitous about its physical and mental health. It is too late to play with sanitary reform, and the time has gone by when the public mind stood in need of special enlightenment as to what that includes and implies. True wisdom will hasten to blot out the declaration that the session which closed on the 13th inst. was "a crucial one," and a discreet "political conscience" must defer to a more propitious moment the boast of having successfully performed "the operation known as 'redeeming your pledges.'"

◆

DR. WM. RUTHERFORD in his recent address in Physiology—or, as it is still designated in the medical schools of Scotland, the Institutes of Medicine—grappled with the question of Vivisection. He was not content with touching upon a subject which, in his opinion, only required to be firmly grasped in order to deprive it of any injurious effects on the future of physiological and medical science. Dr. RUTHERFORD maintains that a great and deplorable error was committed when the unreasonable clamour of the anti-vivisectionists was met in a spirit of compromise, instead of one of stern resistance. Speaking to the members of the British Medical Association, he said that he need scarcely remind them that physiology is an experimental science. Apart from experiments which are the result of artifice, disease and accident are constantly bringing about conditions which partake of the nature of experiments, and are sometimes of great physiological significance. Still, this teaching of disease and accident leads us but a short way, and the pursuit of physiological truth by their aid is often an uncertain, devious, and complicated method. It is excessively difficult to analyse the effects of disease, and to separate the phenomena from one another sufficiently to attribute them to their respective pathological causes, or to precisely apportion the share which this or that structural change has had in their production. On the other hand, the difficult task of pathological analysis grows less as physiology advances. Dr. RUTHERFORD was able to draw a truthful and effective contrast between the very imperfect and indirect theoretical method of physiological instruction in the past and that by demonstration and experiment at the present time. No one can doubt for a moment that the reasoning, critical faculties are educated in the proper sense of the term, and that far more real, definite, practical knowledge is acquired, where men are trained to see and examine for themselves the experimental evidence on which such knowledge rests. Dr. RUTHERFORD maintains that this critical and definite knowledge regarding animal mechanism cannot be attained unless students be shown experiments on living animals; and he strongly condemns the pretensions of anti-vivisectionists, their unceasing clamour, and the impetus which recent attempts at legislation have given to such pretensions. As our readers are aware, we have all along maintained that a good deal of ignorant presumption and a spirit of insincerity and exaggeration have been displayed by the opponents of animal experimentation; but on these grounds alone, if for no other reasons, we held that it would be desirable that the question should be calmly and dispassionately investigated by a properly constituted commission, on which the claims and objects of science were adequately represented. In the minds of many very able, educated, and conscientious persons grave doubts exist as to the objects, extent, and nature of the experiments carried on in this country, and as to how far they are justifiable. It is necessary that a cloud of ignorance and prejudice should be dissipated, in the first place; and, in the second, we thought, and we continue to think, that, as there is a responsibility connected with the taking of life and the infliction of pain, it is a very legitimate and desirable subject for examination whether the limits of justifiable animal experimentation can be defined. It is admitted on all hands that we are justified in taking the lives of the lower animals or inflicting pain on them under certain circumstances. It is the law of nature universally followed in the animal world, and it is a necessity of man's existence. Moreover, sportsmen do not hesitate to inflict pain and death in the pursuit of a selfish gratification, and Dr. Rutherford was therefore able to use this argument with effect when he declared that the pain produced in all the physiological experiments in this country in the course of a year is as nothing when compared with that inflicted upon animals by the members of Her Majesty's Lords and Commons in an autumn holiday. It is, consequently, not for sportsmen to be the first to cast a stone at the vivisectionists. It may be argued that in the case of sport the animals killed serve for food; that they have a chance of escape; that there is no deliberate intention to inflict pain, but to kill; and that the animals hunted or destroyed are, generally speaking, useful for food, or are themselves destructive or injurious to man and other animals, or would become so if they propagated their kind unrestrictedly. On the other hand, there is the sentimental objection to vivisection arising out of a natural repugnance to experiments undertaken in cold blood on horses, dogs, and cats, the faithful companions and servants of men, with a deliberate foreknowledge that some experiments will cause much, and it may be prolonged, pain to the animals subjected to them, although the ultimate object may be the relief of pain and the furtherance of scientific discovery.

We confess that we think Dr. Rutherford presses his principles too far when he argues that, teaching by demonstration being the most successful method, we are therefore always warranted in having recourse to it. Physiology and chemistry are both experimental sciences. The chemical lecturer can have no hesitation about employing any number of experiments, or of repeating them indefinitely to illustrate every step he takes; but we may fairly assume that the physiologist would be restrained by the thought that the materials with which he has to deal are not so much inert, lifeless matter, but sentient living things. We hold, therefore, that it would be both unnecessary and cruel to demonstrate every physiological truth by experiment, or to repeat indefinitely the same experiment simply because by such demonstrations the lecturer could make his teaching more definite, precise, and valuable. If, as Dr. Rutherford avers, all the experiments on the higher animals that are really required for the purpose of education can be performed painlessly with the aid of narcotics, then, of course, he takes away the sting. But we do not for one moment believe that Dr. Rutherford would lend the weight of his authority in support of all the alleged practices of Professor Schiff, for example. Indeed, on a careful perusal of Dr. Rutherford's remarks, it will be seen that he fully admits narcotics should be used whenever it is possible to do so; and that he acknowledges it is not necessary for a sound physiological education that students be shown *all* the experiments that are needed to demonstrate physiological truths, but only such as directly affect cardinal points of physiology. We do not doubt that the subject, regarded in a legislative aspect, is one of extreme difficulty; but that is no reason why the attempt should not be made to ascertain the extent to which experiments on animals are carried on in this country, the conditions under which they are undertaken, and the persons by whom they are performed. The British Medical Association, we believe, itself set forth some years ago the conclusions which it had arrived at in this matter after it had been investigated by a committee; and we cannot see that any reasonable objection can be urged against a similar investigation being undertaken by a Government Commission at the present time, to whose deliberations the matter had better meanwhile be left. It is neither by compromise nor by stern resistance that the objections of a large body of influential persons can be overcome, but by a careful inquiry as to the truth or otherwise of the allegations against the practice of vivisectionists, so as to determine, if possible, the limits within which animal experimentation is right and justifiable.

Annotations.

"Ne quid nimis."

MENINGITIS OR TYPHOID.

The account which a correspondent has furnished of a recent medico-legal case in the North of England will be perused with considerable interest. The differential diagnosis between meningitis and typhoid fever, on which it turned, is a not unfrequent clinical problem of considerable difficulty; and it has before now, if we mistake not, formed the subject of discussion in a court of law. It is rarely, however, that the pathological appearances in such a case afford ground for continued difference of opinion. That it was so in this instance is not, we think, very creditable. The case would appear to be sufficiently clear. A man died on the seventeenth day of an acute illness, of which intense headache, delirium (both continuing till death), constant vomiting, confined bowels, and convulsive movements in one arm, were the main characters; the illness beginning a few weeks after a blow on the head, and the two being connected by continuous head discomfort. The post-mortem appearances in the head, though not very distinctive of meningitis, were compatible with it; but those in the intestine were, according to our received opinions, quite sufficient to exclude typhoid fever. Death on the seventeenth day of typhoid fever has always hitherto been accompanied by intestinal ulceration, and in this case there appears to have been no more evidence of intestinal irritation than the administration of a purgative would account for. The surgeon to the Railway Company, being two hours late at the post-mortem examination, could give no evidence of value as to the morbid appearances, and the verdict was very rightly given for the plaintiff.

OFFICERS OF HEALTH.

The report of Colonel Henderson contains, under the head "Common Lodging-houses," a paragraph exceedingly complimentary to officers of health. He says: "During the late epidemic of scarlet fever in the metropolis, which was of so severe a character as to call for special attention and advice from the medical officers of health as to the precautions necessary to be taken to prevent its further spread, I can with pleasure state that only four cases occurred in registered common lodging-houses, which is a subject of congratulation when it is remembered that about 27,000 persons are accommodated, most of them of the poorest class." This is high praise, and comes opportunely as an encouragement to a laborious and most earnest class of public servants whose efforts for the general welfare are not always, or, perhaps we may say, even commonly, appreciated. The intervention of officers of health is too frequently looked upon with some dislike and suspicion by private practitioners. If it could be arranged to pay officers of health adequately for their services, and to relieve them wholly from private practice, one of the most serious obstacles to their usefulness, as a staff specially organised to crush out disease, would be removed. It would be well if the intervention of skilled sanitarians could be secured immediately an epidemic occurs; and if, without in any way, either sentimentally or practically, interfering with the medical man in attendance, they were able to direct and enforce the precautions necessary to isolate cases, and exterminate the active causes of "infectious" or "contagious" disease. But it is indispensable that medical officers of health, to be widely and sufficiently appreciated, should not themselves be practitioners. It is a mere question of money whether the preservation of public health is confided to a staff of special experts, or left as an unrequited service to be rendered, willingly enough, but under the pressure of more general daily business, by a profession always overworked and commonly underpaid. It is not worthy of a great people or a wise State to leave its vital interests to be thus vaguely and spontaneously protected. Public health is worth paying for. It is worth as much as lighting, paving, or safeguarding our streets. We do not expect these services to be rendered for nothing; why should we expect men who are busy curing disease to devote time and effort to prevent it? Society has recognised the need of a staff of officers of health; it will be wiser and cheaper in the long run to pay them sufficiently to make the service thoroughly skilled and exclusive—a duty and a profession, apart by itself.

THE COLOSSEUM A SANITARY NUISANCE.

THE above announcement seems a startling one, but it has a certain foundation in fact. In the course of the excavations carried on under the eye of the Commendatore Rosa to determine the true arena of the Colosseum, many fragments of columns, capitals, plinths, and other decorative objects were found; and furthermore, at the depth of twelve metres, the *specus emissarius*, or reservoir and conduit for the water with which the amphitheatre was flooded on the occasion of *naumachiæ*, or mock sea-fights. This *specus emissarius* also received, through its upper trunk, the subterraneous water of the Esquiline, Celian, and Palatine hills, and carried them by its lower trunk through the valley between the Celian and Palatine, towards the Circus Maximus till it debouched in the Tiber. These trunks and their feeders having in the course of centuries become choked up, the water supplied to them has filtered into the surrounding soil, till at the depth of a few metres you have only to dig and, as in the Forum and the Campus Martius, water bubbles up freely. The Colosseum, forming a kind of basin, soon yielded water during the excavations, and in such quantity that hydraulic pumps were in constant requisition to enable the workmen to proceed. Now that the excavations have for the time been suspended the pumps have not been in play, and so the water has accumulated till quite a lake has been formed in and around the Colosseum, and the Romans are in terror lest the exhalations from it should poison the neighbourhood. By order of the Minister of Public Instruction, accordingly, a commission, consisting of Drs. Ratti, Lameuzi, and Carlucci, have investigated the apprehended evil at its source, and have, in an elaborate report, formulated the reassuring opinions—1st. That the water accumulated within the Colosseum can cause no injury to health, because it is not stagnant, but, thanks to the old *specus emissarius*, still runs, and is renewed, being taken up by the surrounding soil. It is open to the air and atmospheric action, while there are no confervæ or lacustral vegetation on its surface, but, on the contrary, it is clear and even potable. 2nd. That, though thus far innocuous, the water must have more rapid and fuller vent; and this can easily be afforded by the Government engineers. 3rd. That with such accelerated flow the water, tapping as it does the Esquiline, Celian, and Palatine, will improve the soil of those localities by draining them far more thoroughly than hitherto. 4th. That during the prevailing heats the hydraulic pumps are better idle, as their active play would only expose a larger area of mud to exhale freely in the sun. 5th. That outside the Colosseum the shafts sunk by the excavators, and more or less welling up water, had better be closed, as not immediately drained off by the *specus emissarius*. 6th, and finally. The turned-up soil before the Colosseum, being imperfectly drained, particularly below the Temple of Venus and Rome, and around the Meta Sudans and the Arch of Constantine, and even now becoming a quagmire, must be well sprinkled with lime and covered with gravel, so as to suppress the effluvia already too perceptible to the wayfarer. And so ends the Roman physicians' report, which has allayed the fears of a rather susceptible neighbourhood, and reinstated in public favour their grand old patient the Colosseum.

INJECTION OF QUININE INTO THE TRACHEA IN INTERMITTENT FEVER.

IN some cases of the most pernicious forms of intermittent fever the stomach is so irritable that it is useless to administer quinine by the mouth, as it is immediately rejected; and the state of the circulation in the cutaneous capillaries is such that little or no absorption would take place were it administered hypodermically. In such instances great and immediate benefit may be derived from the injection of solution of quinine into the trachea, as appears from the very interesting and remarkable cases recorded by Claude Bernard, in his recently published "Leçons sur les Anæsthésiques," as having occurred in the practice of Dr. Jousset of Bellesme. One of these cases, much curtailed, was as follows. Some years ago Dr. Jousset, travelling in the northern part of the Greek Archipelago, was called in the morning to see a Greek child, aged twelve, who was seriously ill. On arriving, he was informed that the child was delicate and liable to febrile attacks, but had been in her ordinary health the day before, when she had been playing with other children. In the evening she had suddenly become pale and shivery, and the parents thought her dead; but after two hours or less she had partially recovered and fallen into a deep sleep. In the course of the night she had two more fainting fits. When Dr. Jousset saw her she was lying on a thin mattress on the floor, extremely pale, with deep sunken eyes—in a word, like death. The respiration was scarcely perceptible; the pulse from 38 to 42, very feeble. Slight indications of intelligence still remained. On auscultation coarse râles were heard. The belly was soft, the liver normal, the spleen very large. M. Jousset diagnosed it as a case of malarial fever of bad type; and he immediately endeavoured to give the patient some quinine, but vomiting was induced, and syncope. Having previously had a successful case, he at once proceeded to inject a solution of hydrochlorate of quinine into the trachea. He inserted the trocar of a Pravaz' syringe into the middle of the trachea, between the first and second cartilaginous rings. A little difficulty was experienced, as the thyroid gland was large, and he only satisfied himself that the point was free by blowing through the canula. The pulse was now 31. No effort at coughing was made, and he thought she had succumbed. Five minutes after the pulse was 40. The limbs were now covered with warm flannel and light friction made. In ten minutes the pulse had risen to 45, and an involuntary evacuation occurred. She murmured some words. In thirty-five minutes she asked for some drink. She complained of intense pain in the head, which, however, was not hot. In an hour the pulse had risen to 96; and shortly afterwards she was in her ordinary health.

THE PRESCRIPTION OF "SPOONFULS."

THE coroner for the City of Exeter has been the means of entering on the death-register a strong and useful protest against the time-honoured practice of prescribing medicine by the spoonful. It is pretty generally known that the teaspoon and tablespoon of the present day are of far from fixed capacity, and may, moreover, be said to average nearly double the size that was in vogue little more than a quarter of a century ago. If, therefore, the terms teaspoon and tablespoon were even qualified by the words "old" or "new style," some guide would be given as to the quantities intended; this, however, is seldom the case. A month or two since the infant daughter of a coach-trimmer, aged nineteen days, died in Exeter, under conditions that suggested poison as the cause. The result was an inquest, and a chance examination of the Exeter death-register the other day for another purpose, showed that the cause of death of this infant was returned in the coroner's certificate in the following manner:—"Congestion of the lungs, accelerated by an overdose of opium, innocently administered by her mother from a *modern* teaspoon containing two drachms, instead of from a teaspoon of older date, containing one drachm." The evidence given at the inquest is not before us, and therefore we are unaware of the form of opium that was administered to the infant, or under whose advice it was given. The probability is that the mixture was one of those deleterious compounds known as "soothing syrups," and that the "directions for use" prescribed the teaspoonful. However this may have been, it is beyond dispute that the term "spoonful" no longer signifies a quantity which is sufficiently definite and intelligible to the public, and should therefore be abandoned.

URBAN DEATH-RATES IN ENGLISH AND SCOTCH TOWNS IN JULY.

THE Scottish Monthly Return of Mortality in the eight principal towns of North Britain is in some respects fully as valuable a contribution to vital statistics as the Registrar-General's Weekly Return in England. The summary of twelve monthly returns gives correct statistics for a year, whereas from weekly returns accurate numbers for a year can never be obtained. On the other hand, the promptness of information as to mortality from zymotic diseases in the eighteen large English towns contained in the weekly returns has a well-defined value, which more than outweighs the greater completeness of detail in the Scotch monthly return. One of the objections to the want of uniformity in the system of publication north and south of the Tweed is the difficulty of comparing the results for the Scotch and English towns. We propose to institute a brief comparison for July by using the figures from the Scotch monthly, and from the English weekly returns relating to the twenty-eight days ending 31st July. The eighteen English towns have a present estimated population of 6,682,033, while that of the eight Scotch towns is but 1,171,989. The annual death-rate in the English towns during the four weeks of July was 22·7 per 1000, whereas in the Scotch towns the rate for the month was 23·5. As regards the mortality from the seven principal zymotic diseases, it was equal to 5·5 in the principal urban population of England, and did not exceed 4·8 in that of Scotland. The zymotic death-rate in England during July is governed by the rate of infant mortality, and the annual death-rate from diarrhœa in the eighteen English towns during that month was 2·7 per 1000, whereas in the eight Scotch towns it did not exceed 1·3 per 1000. Excluding diarrhœa from consideration, the death-rate caused by small-pox, measles, scarlatina, diphtheria, whooping-cough, and fever, was 2·8 in the English towns and 3·6 in those of Scotland. Among the English towns the death-rate from all causes ranged from 14 and 16 per 1000 in Portsmouth and Norwich, to 29 in Nottingham, Salford, and Newcastle-upon-Tyne. In the Scotch towns the rate was only 16 per 1000 in Aberdeen, and ranged upwards to 25 in Greenock, 26 in Glasgow, and 31 in Paisley. The death-rate from the seven zymotic diseases was as low as 0·8 in Portsmouth, while the highest rate was 9·8 in Salford. The zymotic rate in the Scotch towns ranged from 2·0 per 1000 in Aberdeen, to 7·1 in Greenock and 7·8 in Paisley. We can only now apply one more comparative test to the mortality statistics of the large English and Scotch towns during July. The death-rate from various forms of fever, of which typhus and enteric are the most fatal, was equal to 0·40 per 1000 in the eighteen English, and to 0·58 in the eight Scotch towns. The comparison is in favour of the health or sanitary condition of the English towns on each point, excepting alone the death-rate from diarrhœa, which in July was nearly twice as high in England as in Scotland. It is impossible here to discuss the cause of this greater fatality of diarrhœa south of the Tweed; the intimate relation between temperature and the mortality from this disease must, however, be remembered, although there is reason to believe that in the poorer classes more intelligent care of infant life is found in the Scotch than in the English mother.

ABEYANCE OF VACCINATION IN KEIGHLEY UNION.

WHILE those who firmly believe that vaccination secures the nearest known approach to immunity from the worst forms of small-pox are anxiously awaiting the result of that tedious form of prosecution of the Keighley Board of Guardians by *mandamus*, few appear to be aware of the present all but complete abeyance of vaccination within that union. Previously to 1873 there appears to have been no organised opposition to vaccination in the neighbourhood, at all events the number of defaulters was then inconsiderable. Between the beginning of 1873 and the middle of 1875, however, of about 4421 children born in the union, no less than 2344 remain unvaccinated; neither have all the other 2077 children been vaccinated, as considerable numbers died before the statutory six months from birth had elapsed, until which they are not classed as defaulters. It is also to be noticed that, in spite of the small-pox epidemic, which usually causes a large increase in the number of vaccinations, the defaulters were considerably more numerous in 1874 than in 1873. At a recent meeting of the Keighley Guardians, Dr. Macnab, one of the public vaccinators, resigned his appointment because he had attended at the vaccination stations four times a month during the year, and not a single case had been presented to him for vaccination! This board, at the same meeting, passed a resolution, with the help of the chairman's casting vote, not to receive some statistics of small-pox and vaccination drawn up by the medical officer of the workhouse, because he refused to place his books in the hands of the guardians, in order that they might test the accuracy of his figures, and investigate the cases. Such an investigation could not, however, be satisfactory after the death and burial of so many of the small-pox patients. So long as the anti-vaccination agitators insist upon believing that the vast majority of the medical profession and of the intelligent public are conspiring to maintain vaccination by false and "cooked" statistics, it is useless to attempt to reason with them.

MEDICAL AND SANITARY FATALISM.

It is quite time that an urgent protest was entered against a species of fatalism which is now finding its way into reports of certain medical officers of health, and is leading them to attempt to forecast not only the prevalence of disease, but the proportion of deaths that will result from it. The Peculiar People confess to a belief that disease is inevitable and invincible, only yielding to prayer; but what becomes of our boasted medical and sanitary progress, if epidemics are to be professionally prognosticated to run the same course and to lead to the same mortality as in times gone by? It may answer a useful purpose for medical officers of health, in order to stimulate their sanitary authorities to continued activity, to warn them that the study of what it is now the fashion to call waves of disease leads to the conclusion that we may soon expect an epidemic of one or other disease. Crying wolf, however, is a dangerous weapon—it is a two-edged sword that cuts both ways. Dr. Tripe, in his recently-issued report upon the sanitary condition of Hackney, says that during 1875–6 a very much larger mortality from scarlet fever must be expected. The medical officer of health for Hackney is perfectly justified in calling attention to the probability that if the epidemic of scarlet fever in London, which has more or less prevailed since the latter part of 1874, is to run the course of previous epidemics, its fatality may revive later in the year. Is it not fair, however, to express a hope—nay, a belief—that the sanitary condition of London has improved, and that epidemics will continue to show a declining fatality? Did not the cholera epidemics of 1832, 1849, 1854, and 1866, successively show a marked decrease in mortality in London? This attempt to prophesy increased fatality of scarlet fever appears to us to show a want of confidence in our increased power to deal with epidemics which is especially out of place in a medical officer of health's report.

URINALS.

Although London is supposed by some fortunate persons to be empty at the present time, a section of the population is still compelled to exist within its precincts, and, with a temperature of considerably over 70° Fahr., to endure many mundane inconveniences. Among those of an offensive character may be classed the metropolitan urinals. It is an unsavoury subject, but we are bound to declare that these indispensable establishments, whether in the street, at the railway station, or on the river, are for the most part in a superlatively nasty condition, and sometimes intolerably stifling. The individual who invented and fabricated the elaborate receptacles of nastiness fitted in most London urinals, can by no means be classed as a benefactor of mankind. The pan itself (utterly superfluous and useless) is usually coated with a foul deposit, the exit pipe blocked up, and flow of water *nil*, as though the officials were chiefly concerned in reserving specimens for clinical examination. These places are rendered still more hideous by an attempt made in some cases to ornament with coloured tiles, patent ironwork "treadles" and the like, the latter of which soon, of course, rust, and the levers get out of gear. According to our own observation the only clean and wholesome place of the kind at the present time is to be found at the Victoria Station of the London and Brighton Railway. It is absolutely roofless, the compartments are placed back to back, no vile pan arrangement exists, slate only is used in the construction of the urinal, and a continuous stream of water flows into a wide gutter beneath, laid at a good incline. If urinals constructed in this way are properly cleaned out several times in the day (according to frequency of occupation), and *liquid* instead of solid deodorisers or disinfectants used, and the abominable pans abolished utterly, no accumulation need take place (if the drains below are free), and we who are compelled to remain during the dog-days in this "deserted village" would possess one nuisance less. It appears, to us, indeed, that a periodical examination of all such places, including those on the steamboat piers, should be made by the officers of the various sanitary authorities.

PARIS AND LONDON IN 1874.

The *Bulletin récapitulatif de Statistique Municipale*, relating to Paris for 1874, has just been issued by the Préfet de la Seine. It corresponds with the Registrar-General's Annual Summary for London, and although its statistics are published in a far more elaborate form than those for London, they afford the means for a comparison between the vital statistics of the two largest cities of the world. The population of London in 1874 was very nearly double that of Paris; the density of population in persons to an acre was, however, only 44 per acre in London, whereas it was 96 in Paris. The marriage-rate was 8 per 1000 in London and 10 in Paris; the birth-rate 35 in London and 29 in Paris; and the death-rate 21·6 in London and 22 in Paris. Whereas the marriage-rate in Paris exceeded that in London by 25 per cent.; the birth-rate in Paris was 20 per cent. below that in London. The death-rate in the two cities in 1874 showed little difference, and yet, in consequence of the variation between the birth-rates, the natural increase in the population during the year, by excess of births over deaths, was equal to nearly 14 per 1000 in London, whereas it was not more than 7 per 1000 in Paris. Notwithstanding that the marriage-rate in Paris considerably exceeds that in London, the proportion of illegitimate births in Paris was nearly 27 per cent., while in London it is only about 4 per cent. With regard to the mortality statistics, the annual Paris Bulletin contains information in far greater detail than the London Annual Summary. The rate of mortality is given for each of the twenty arrondissements, and for each of the eighty quartiers into which Paris is divided. In the twenty arrondissements the death-rate in 1874 ranged from 15 per 1000 to 27. It is somewhat remarkable that in the arrondissement in which the density of population is greatest in Paris—namely, more than 300 persons per acre—the death-rate did not, in 1874, exceed 16 per 1000. London figures show a very different result.

THE LOCALISATION OF SENSORY CENTRES IN THE BRAIN.

At the recent meeting of the British Medical Association, Dr. Brunton read a paper, communicated by Dr. Ferrier, containing an "Abstract of Experiments on the Brains of Monkeys, with special reference to the Localisation of Sensory Centres in the Convolutions." The experiments, which were conducted by trephining and the destruction of the sensory centres by means of a red-hot wire, led to the following results. These centres are bilateral, so that when one of the centres of touch was destroyed, there was loss of tactile sensibility in the corresponding half of the body. Stimulation of the centre of hearing caused the animal to prick up its ears as if it heard something, while destruction of the whole of this centre rendered the creature totally deaf. Destruction of the centre of vision corresponding to one eye (e. g., the right) only rendered the animal temporarily blind in that eye, the function, after twenty-four hours, being carried on by the opposite centre. In the discussion that followed, Dr. Nairne pointed out that other observers had arrived at conclusions different from those of Dr. Ferrier, and that the brain of a monkey could not be taken as exactly similar to that of a man; but Dr. Brunton thought the mistake made by German and other investigators who differed from Dr. Ferrier was, that they took the brains of animals lower even than the monkey to correspond with that of man. M. Dupuy had arrived at different results. He said that he had found that when the centres of motion on one side of the brain were removed, paralysis followed for a short time throughout the corresponding part of the body, but that when the centres were removed from both sides of the brain there was no paralysis at all.

THE COLLEGE OF PHYSICIANS AND PSYCHOLOGICAL MEDICINE.

The Royal College of Physicians of London has instructed its Registrar to prepare and submit a regulation to the College, "That students who wish to qualify for the examination for the membership or licence of the College may substitute, if they so desire, a three months' course of clinical instruction in the wards of a lunatic asylum for the same period of attendance in the medical wards of a general hospital." The College, by this step, does no more than recognise adequately the importance of psychological medicine. It has the merit of exacting from its candidates a pretty good measure of hospital practice. In the case of candidates for the membership attendance is required for three winters and three summers on the medical practice of a hospital, and for three winter and two summer sessions on the surgical practice. Almost the same demand is made of candidates for the licence. Clearly three months of this period might not unprofitably be spent in the study of mental disease. Even for purposes of general practice the knowledge so acquired would be useful, and for those contemplating more exclusive attention to psychological medicine the knowledge would be invaluable.

THE COAGULATION OF THE BLOOD.

M. Glénard, of Lyons, finds that the influence of foreign bodies in determining the occurrence of coagulation in blood is the less, the closer their physical texture resembles that of the physical texture of the bloodvessels. Coagulation is the indication of the death of the blood. It is capable, according to M. Glénard, of being revivified as long as it remains fluid in a bloodvessel even away from the body. The blood of an ox can be transfused into a dog with success six hours after removal from the body. The coagulability is retarded, but not destroyed, by concentration of the blood, which acts in a manner analogous to the admixture of salt. An analogy may be drawn between the effect of deprivation of water upon the rotifera. Blood contained in a bloodvessel which had been removed from the body of an animal may be slowly dried, and when the vessel has a horny consistence, the contained blood may be powdered and subsequently mixed with water, in which it forms a solution capable of undergoing spontaneous coagulation, even after it has been filtered.

BLIND USE OF DRUGS.

Heads of families who are in the habit of indiscriminately using patent medicines for all sorts of affections and all ages should be warned of the disastrous effects which sometimes result from the ignorant administration of drugs, valuable in themselves and when given under proper medical advice, by the facts elicited at a recent inquest before Mr. Bedford. A child, aged six months, suffering from diarrhœa, was given a dose of chlorodyne by her father. Death soon after ensued. Although, after a post-mortem examination, an opinion was given that diarrhœa was the cause of death, it is easily conceivable that a very small dose indeed of the preparation would prove fatal to a baby. Chlorodyne contains opium, chloroform, and prussic-acid, ingredients that should teach any one of the risk of giving it to children under a certain age.

NEW MEDICAL SCHOOL IN GLASGOW.

We understand that the managing body of the Glasgow Royal Infirmary are about to receive authority, under a new supplementary charter, to establish in connexion with the hospital a medical school. The opening of the Western Infirmary, in close connexion with the University, has had the foreseen and natural effect of draining from the older hospital the greater number of University students. It says much for the energy of the directors of the Royal Infirmary that they have taken the earliest opportunity of obtaining powers to render the great resources of their hospital for practical teaching more largely available for students of medicine. The new school will have this advantage over the existing extra-mural school, that the University authorities will be able and, we have no doubt, glad to exercise the powers they possess of recognising attendance, within certain limits, on the lectures delivered at the infirmary as qualifying for graduation. The sole plea on which the University has hitherto refused to accept the certificates of the teachers of Anderson's University—viz., the assumption of academic status implied in the name of the institution—will not exist in the present case. We shall watch the establishment and progress of the new school with kindly interest and the best wishes for its success.

MISPLACED BENEVOLENCE.

A lay contemporary states that "Adelina Patti has evinced her deep and earnest sympathy with sufferers from throat disease by promising to return from the Continent some time in September for the purpose of laying the foundation stone of the Throat and Ear Hospital in Gray's-inn-road." Someone should inform the fair cantatrice that there is not the slightest need for establishing an excrescence of the sort named. Patients suffering from throat and ear affections are skilfully treated at our general hospitals. If the Marquise de Caux is desirous of gracing with her presence—which of itself would ensure a large measure of pecuniary success—the inauguration of a new medical charity, let it be one which receives the commendation and support of the profession.

DRUNKENNESS IN IRELAND.

The Report of the Inspector-Generals of Irish Prisons for 1874 shows an enormous increase in the amount of imprisonment for drunkenness in that country. The number of commitments to borough and county gaols has increased progressively from 6645 in 1867, to 14,008 in 1874. These represent, it appears, a more severe degree of punishment rather than a corresponding increase in the amount of drunkenness. Short periods of imprisonment, under forty-eight hours, are spent in the local bridewell, and are not included in the report. The magistrates have endeavoured to lessen the amount of intoxication by lengthening the period of imprisonment for it, as they are able to do under the new licensing Act. But the repetition for each offence of a comparatively short period of imprisonment is apparently, as might be expected, of no effect. It only, as the Inspector-Generals point out, enables the drunkard to recover from the effects of his debauch, and sends him out ready, and probably much inclined, to renew it. They recommend that habitual drunkenness should be visited with a term of imprisonment sufficiently lengthened to afford some chance of permanent recovery. But it is improbable that such a measure could be carried out. The moral of the report and recommendation is the urgent need for institutions which would not be prisons, in which the habitual drunkard could undergo a seclusion which would be remedial rather than directly punitive, and in which he might have some chance of recovery.

"RAILWAY SHOCK."

THE remote effects of shock on the nervous system constitute a grave financial drawback to the prosperity of some of our railway companies, and afford a ground for not a little divergence of opinion, out of which the unfortunate sufferer does not always obtain his due. The occurrence of a period of perfect health between the receipt of the accident and the supervention of the nervous symptoms is a condition to which the mind of a jury is particularly obtuse. They are more conscious of the promising field for simulation which this class of symptoms afford than of their possible reality and gravity. It is no doubt right that this should be the case to some extent. But a very slight degree of nervous breakdown may be sufficient to entirely disable the sufferer from following his accustomed employment. This was the result of a severe shaking in a case tried in the Sheriffs' Court a few days ago. The plaintiff was a commercial traveller, whose income depended on his constant use of railways, and it was alleged that the pain and nervous excitement which persisted two years afterwards incapacitated him from travelling to an extent which warranted heavy damages. The evidence, however, was not sufficient to satisfy the jury that more than very moderate compensation was indicated by the facts of the case.

PARENCHYMATOUS HEPATITIS.

AT a recent meeting of the Société de Biologie M. Cornil gave an account of the changes met with in the livers of patients who had died from parenchymatous hepatitis supervening in the course of puerperal fever, leukhæmia, typhoid fever, and variola. In all these cases he found similar changes to those which he had previously described as taking place in cirrhosis. The smallest biliary capillaries were filled with epithelial cells, finally obliterating the channels altogether. These changes being most marked in the peripheral ducts of the lobule, it is easy to account for the production of jaundice in these cases, the bile contained in the central canaliculi not being able to escape into the interlobular ducts. It will be seen that this explanation of the occurrence of jaundice in febrile affections is based on the view of there being mechanical obstruction to the outflow of bile; and whereas this obstruction is usually attributed to catarrh of the larger hepatic ducts, it is, on these researches, simply placed further back—viz., in the periphery of the lobules themselves.

SANITATION IN LEICESTER.

IN consequence of the prevalence and fatality of diarrhœa in Leicester during the last few months, the sanitary authority of the town determined to institute an inquiry into the cause and condition of such an abnormal visitation of disease. Dr. Buck and Mr. Franklin have been appointed to carry out the work of investigation, for which they are to be rewarded. They are instructed to visit every house in which the death of a child under five years of age from diarrhœa has occurred since the 1st July, and to ascertain particulars of each illness, and whether deceased had received regular medical treatment. The important questions of diet, the health and occupation of the parents, and the condition of the drainage are also to be worked out. The inquiries are to extend to all localities of the town where infantile diarrhœa is now prevailing, although no death has occurred, and a report is to be made with as little delay as possible. We have no doubt that the energetic action taken by the health authority will be the means of bringing to light the origin of the disease, and of indicating measures for its suppression.

THE CHAMELEON.

M. BERT has recently made some curious observations on the chameleon, which apparently indicate a very unusual relation of the two halves of its nervous system. Having removed the right eye of one of these animals, he produced, by irritating it, a rapid change of colour on the left side of the body. The right side was much longer in changing its colour, and did not acquire the same tint. He subsequently removed the left eye, and found that then the change of colour on irritation was regular and identical on the two sides. In another experiment he found that one of these animals, the right cerebral hemisphere of which had been removed, used only the left paw. On the subsequent removal of the left hemisphere it presented very active and bilateral reflex movements.

MAJOR BOLTON, in his last monthly report of the London water-supply, expresses an opinion that the contamination of water from the gases generated by sewage is of more frequent occurrence than is generally supposed. The gases are extremely liable to flow back into the cisterns and become absorbed by the water unless the overflow pipe is brought outside the house and the end left exposed to the air, instead of being carried into the drain. Although this simple and effective plan has been advocated over and over again in our columns, the importance of the subject warrants us in again impressing upon householders the necessity for its general adoption. The cisterns should be frequently cleaned out, especially after periods of flood and turbidity.

THOSE whose hard fortune compelled them to travel by the Underground Railway during the very hot days we experienced in the early part of this week must have realised the sensation of taking a Turkish bath, without being benefited by the processes of shampooing and washing. When these railways were first started, it was promised that the ventilation of the tunnels would be gradually improved as the system became developed. No real improvement, however, has been effected in this direction, and the atmosphere along the line is as foul and vitiated as ever. In all seriousness, we think the offensive acrid smoke and stifling heat inseparable from a journey on the Metropolitan should be avoided as much as possible by weakly persons.

FOUR years ago it was determined to commemorate John Hunter's long residence in Kensington—a period of nearly thirty years—by placing a memorial window in Kensington parish church. The last appeal for subscriptions is now being made. The sum in hand for the purpose amounts to £80, and further subscriptions (limited to 21s.) are solicited by Mr. Frank Buckland, 4, Old Palace-yard, Westminster, and Mr. J. J. Merriman, 45, Kensington-square, W. A list of donors will be published in the course of the year, and a drawing of John Hunter's house and grounds forwarded to each subscriber. Hunter will be worthily associated with Newton, Addison, and others whose memories are similarly preserved in the church.

THE existing Public Health Acts of 1872 and 1874 prohibit sanitary authorities and other parties from terminating their sewers in water-courses. Dr. Cameron, of Dublin, however, in a recent report on public health, considers that there are great difficulties in the way of disposing of sewage, and believes that in many cases it will be far the cheapest plan to allow the rivers to remain, as they have always been, the great natural drains, or main sewers of the country, and to procure supplies of pure water from a distant source.

WE are informed that the Royal Commission on Copyright has been definitely settled by the Government, and will, it is expected, meet to take evidence about January next, under the presidency of Earl Stanhope. The objects of the Commission will be to see how far, and in what direction, international, colonial, and domestic copyright can be improved. The subject is one of considerable interest to medical authors, some of whom will, we hope, be called before the Commission.

IN London 1483 deaths were registered last week, including 1 from small-pox, 36 from measles, 87 from scarlet fever, 7 from diphtheria, 50 from whooping-cough, 22 from different forms of fever, and 147 from diarrhœa. Different forms of violence caused 56 deaths, 10 of which were due to drowning. The Asylum District Fever and Small-pox Hospitals at Homerton and Stockwell contained, on the 14th inst., 225 patients, of whom 163 were under treatment for scarlet fever and 6 for small-pox.

THE Secretary of State for the Home Department has directed Colonel Cox, R.E., to hold an inquiry with reference to a complaint of the Lea Conservancy Board, that the purification and disinfection of the sewage matter passing through the sewage works of the Local Board of Tottenham are insufficient. The want of such an inquiry has been felt in the locality for a long time past.

LADY COTTESLOE died a few days ago from the effects of poison taken inadvertently. She was suffering from rheumatism, and, in addition to taking medicine, was using a lotion, which, in an unfortunate moment, she drank in mistake for the mixture. After two days' suffering she died. Her ladyship was seventy-two years of age. We suppose the lotion contained aconite or belladonna.

THE Governors of the Royal Infirmary for Children and Women, situated in Waterloo-bridge-road, have decided on temporarily closing the institution in order to make certain much-needed alterations. A ward capable of holding 25 additional beds is to be added to the building.

DR. HARDWICKE held several inquests this week on bodies where death was directly attributed to overcrowding and want of fresh air. Evidence of a shocking condition of existence was given, and the imperative necessity of an Artisans' Dwellings Act was demonstrated.

WE understand that Mr. Corbett has, in consequence of ill-health, resigned the chair of Anatomy and Physiology in Queen's College, Cork—an appointment that he has most creditably held for a period of twenty-four years.

ACCORDING to recent accounts from Rome, the Pope's health has greatly improved within the last few weeks. His Holiness now does a large amount of work.

WE understand that the epidemic of enteric fever in Müller's Orphan Houses, Bristol, has now been almost entirely stamped out.

Correspondence.

"Audi alteram partem."

THE CASE OF GENERAL REECE, C.B.

To the Editor of THE LANCET.

SIR,—The very singular medico-legal questions involved in the case of the late unfortunate gentleman, General Reece, the publicity given to it by the coroner's inquest held at his death, and the article in THE LANCET of last week, may render some authentic account of his case interesting to the profession.

On the 1st day of July last I was requested to see General Reece. I found him in his own lodgings, a comfortless room without carpet, in almost total darkness, the shutters being perforce closed, as the lower pane of the window had been broken. General Reece received me very politely. We had a long conversation. I gathered from him and from his attendants that on the 17th of March he had had a seizure of some kind in the night, that this was followed by paralysis of the lower extremities, which he erroneously thought was now better. He had two nurses from an institution in the neighbourhood during the whole time. Within the last three or four days they had sent to the same place for a male attendant, the General being beyond their control and having broken the window. Against this man General Reece spoke in terms of great dislike.

He had, besides the paralysis, bronchitis and some symptom of heart disease. I advised his removal to a house in which his son was lodging, some few doors off in the same street. I thought he had been well and judiciously treated by Dr. Broxholm, and his medical treatment therefore remained unaltered. I had no doubt that General Reece was of unsound mind, and that certificates of lunacy were legally indispensable in his removal. These were accordingly signed by Dr. Broxholm and myself. Dr. Wood was also consulted, but was unable to write a certificate, although perfectly agreeing with me in my opinion of the General's mental state.

It was found impossible to remove the General from his house, although Dr. Broxholm and I had thought it practicable the day before. The curious question then arose, Could a patient be legally kept under control without certificates in his own lodgings as he could be in his own house? Upon this the opinion of the Commissioners in Lunacy was obtained, and under their direction an order was made by the son of General Reece, authorising the detention of his father, addressed to Wheeler, another attendant from the same Institute for Nurses. The certificates, signed by Dr. Broxholm and myself, were put in force, and General Reece was placed under the protection of the Commissioners. Dr. Broxholm and I considered the General to be suffering under organic brain disease, and to be partially imbecile, the effect of age and hard service in India. If there could be any doubt as to the correctness of the conclusions arrived at by the constant medical attendant of the General and myself, it may be dispelled by the fact that Dr. Maudsley, on the 13th of July, made an affidavit to the fact that the General was the subject of "senile insanity." After frequent visits I made a similar affidavit about the same date, and these affidavits are confirmed by the "statement" sent up by Dr. Stewart, as the official medical attendant under the statutes of lunacy. Dr. Quain and Dr. Wilks were also consulted in General Reece's case. As far as I know there has been no opinion as to the sanity of General Reece given in opposition to our affidavits by them or any other physician.

On the 12th of July the General died. Mr. Low, his banker and executor, applied for a coroner's inquest, alleging that confinement as a lunatic had accelerated his death. The verdict, as a matter of course, was "Death from natural causes." One or two of the jury (not the coroner, as it was erroneously reported) thought that confinement as a lunatic had been injurious. They would hardly have thus given pain to the General's family if they had known that the employment of such confinement, light as it was, was forced upon them by the exigency of the lunacy laws, and in my opinion could not have been carried out with greater gentleness and skill than it was by Dr. Broxholm. It is significant that Mr. Low should have made the application for an inquiry at the deceased General's own request. It was one of the marked characteristics of the General's infirmity of mind that he thought himself ill-treated by his sons, who, he thought, had kept him in bed, the fact being that he could not walk or even stand up without assistance.

In the opinion of Mr. Low, General Reece was always of sound mind. Upon his representation, the Commissioners in Lunacy made the most stringent inquiries into the case. At his application, judge's orders were freely made to give him access to the patient. At his desire, on the General's death, a coroner's inquest was held, at which Dr. Broxholm was closely examined. A writ of *habeas corpus* was also about to be issued; and, as it was, one of the judges himself went down to see the alleged lunatic, taking with him his own physician, Dr. Langston. It may be presumed that this course was adopted in order that the judge might be perfectly assured of the physical impossibility of the family of General Reece taking him into court. The action taken by the learned judge, Baron Cleasby, proves how much importance he attached to the question, and the promptitude with which he would have acted if he had found it necessary.

Mr. Low may be right; Dr. Broxholm, Dr. Maudsley, and Dr. Tuke, together with the family of General Reece, may be wrong. But it is abundantly clear that nothing has been done, on the one side, inconsistent with the conduct of people of proper feeling acting under the advice of physicians of reputation; nor, on the other side, has there been any difficulty in obtaining the fullest opportunity for investigation, and, if wrong had been committed, of speedy redress.

The case of General Reece shows very forcibly the intense jealousy of our English law of any undue interference with the liberty of the subject, and, with the present legal safeguards, the impossibility of any really sane man being wrongfully treated as a lunatic.

I am, Sir, your obedient servant,

Harrington Tuke.

Albemarle-street, W., August 18th, 1875.

WOOD v. THE MANCHESTER, SHEFFIELD, AND LINCOLNSHIRE RAILWAY COMPANY.

To the Editor of The Lancet.

Sir,—I think this trial, both on account of the medical questions which were raised in its course, and of some incidents in connexion with it, is worthy of notice in your journal, and will be of more than usual interest to the profession. It was brought, as you will see from the accompanying report, by the widow of a farmer, to recover compensation for the death of her husband, which it was alleged was due to the negligence of the defendants.

On Nov. 21st last the deceased was travelling on the company's railway, and as his train was standing still at Conisborough Station an engine and tender ran into it. The deceased was much shaken, and received a blow on the head, which left a contusion the size of a florin, by being thrown against the door of the carriage. He received also minor injuries about his wrist and elbow. Immediately after he got home he complained of pain in the head, and spent a restless night. He was able, however, next day to go to Dr. Seaborne for advice, feeling very unwell. He was given an aperient, and advised to go to bed. The company's medical officer, Mr. Fox, visited the deceased on Nov. 30th, and found him suffering from headache, sleeplessness, and shakiness. There was still the bruise on the temple. Up to Dec. 24th deceased suffered more or less constantly from the same symptoms, at times more or less severe, but on that and the following day he appeared to be so much better that he hoped he had quite recovered his former good health. Indeed, for some days previously the advisability of coming to an arrangement with the company about compensation had been discussed.

Late on the evening of the 25th December, however, the headache and restlessness returned in a more intense form, this time accompanied with vomiting. From that date he kept his bed, Dr. Seaborne attending him, and he was so much worse on January 2nd, that Mr. Lister, of Doncaster, was called in. His symptoms were then, intense headache, persistent vomiting, inability to retain food, constipation (except for two days, after a repeated aperient, of which more will be said), intolerance of light, muscular twitchings, and delirium. He was seen again by the company's medical officer on January 6th, who found him with a pulse of 130; temperature 103·4°; pupils dilated; a dry, brown tongue; pain on pressure in right iliac fossa. There was no rose rash anywhere on body. From this time until the 9th January, when he died, deceased gradually became comatose, with occasional violent delirium, convulsive twitchings, retention of urine, constipation, and dilated pupils. He was apparently partially conscious at times in the midst of his delirium, till near his death.

The post-mortem examination was arranged to be made on the 11th, and was fixed for 10 o'clock, notice of which was sent to the medical officer of the company. He did not, however, arrive till after 12 o'clock, and until, after waiting an hour or more for his attendance, the examination had commenced. It is owing to this unfortunate circumstance that a difference of opinion has existed with respect to the exact condition of the membranes, and the appearances they presented before and after his arrival—appearances which, from the peculiar nature of the case, were apparently the most important feature of the whole.

The contention of the railway company was, that deceased had, since the injury received (and for which they acknowledged their responsibility), contracted enteric fever and died of it.

The medical attendants of the deceased treated him for meningitis, and were of opinion that he died of that disease, and not of enteric fever. What light did the post-mortem throw on it? Did the appearances all point strongly to the one or undoubtedly to the other? And with respect to this part of the inquiry, and as one of the two gentlemen who made the examination, I will first mention those facts which were admitted by all to exist, and then those on which there was some difference of opinion. The conclusions which ought to be drawn from certain given conditions or groupings of facts I will not enter upon, except to indicate what were the views taken, and to give an example of the sort of questions raised, the attempted solution of which was attended with great difficulty to the legal mind. They are, indeed, purely medical questions, which, if they are cleared up, will certainly not be in a court of law. I think I am not wrong in describing the admitted facts of the post-mortem as these:—Lungs slightly congested; old pleuritic adhesions, left side; liver rather congested; heart healthy; kidneys healthy; duodenum, jejunum, and upper two-thirds of ileum healthy; in lower third of ileum intestinal catarrh; congestion and slight tumefaction of three or four of Peyer's patches; no ulceration; mucous membrane smooth and intact over its entire surface; no evidence of hæmorrhage in bowel; considerable quantity of healthy-looking fæcal matter of firm consistence. Spleen variously estimated at from 7 to 10 ounces—not weighed; not unduly soft. On the part of some—*both* who actually made the post-mortem—there are stated to be appearances of recent acute inflammation of brain membranes—viz., thickening and opacity of arachnoid; patches of effused lymph; adhesions in anterior portion of dura mater to the bone, and of both layers of arachnoid; meningeal vessels turgid; brain slightly injected. Mr. Fox, the company's medical officer, who came late, could not admit seeing adhesions or effusion, but admitted seeing several "pieces" or "filaments" between the layers of arachnoid, these not being bloodvessels. This, I submit, is rather an important admission.

So much for the intrinsic facts of the case. Then, in support of the theory of enteric fever, the railway company brought forward witnesses to show that in May last year there was defective drainage in the neighbourhood, and that there was a tank into which the drainage ran, which tank overflowed to such an extent that the overflow might reach a well in a quarry at some distance, from which quarry well the water was fetched which the family of deceased had used; that in May, 1874, there had been three or four cases of fever, probably enteric, in cottages close at hand; that the water had been tested, and that the water from the quarry well contained ·37 of a grain of ammonia per gallon, and some organic matter. This estimate was formed on

January 11th, 1875; no quantitative analysis was made in May, 1874. In opposition to this it was stated that the stratification was such that it dipped towards the tank or cesspool, and that it could only be after a heavy rain that it could overflow to such an extent as to reach the quarry well. It was thus difficult to prove *specific* contamination of the water, of which deceased used very little for drinking. None of the family, ten in number, among whom were six children, had suffered in health, the water being boiled for even washing purposes.

This, then, is the substance of the evidence, and it becomes a question to decide whether the symptoms during life, with the previous history, the post-mortem revelations, and the collateral circumstances of a sanitary nature, go to prove that the deceased died from the effects of injury or of enteric fever. It is really a case of *traumatic meningitis* versus *enteric fever*. Is there any way of deciding authoritatively which it has been? In favour of meningitis are the history of the blow and the nervous shock, headache; symptoms pointing beyond doubt to concussion and irritation of the brain up to the time of his death, with the exception of two or three days (from the 23rd December to 26th December), absence of characteristic rose rash, absence of diarrhœa, absence of ulceration of Peyer's patches after death. Did the *specific* (?) poison of enteric fever step in on those two or three days and go on to a fatal ending? If not then, when? If it did so show itself on the night of December 25th, was it a necessity that ulceration should be present? On this point Dr. Mahomed, of St. Mary's Hospital, is emphatic. If the fever lasted over sixteen days, he would certainly expect ulceration after death. In this opinion he is confirmed by Dr. Ellison and Mr. Wheelhouse. But did the fever, if it was there, last so long? Are there any means of dating accurately the commencement of the fever? In answer to this, Dr. Clifford Allbutt, with the scientific impartiality which would be expected from him, admitted that the early symptoms of enteric fever were very uncertain in duration and kind, and that it was impossible, in a great number of cases, to say when the fever commenced, as, after its first inception, there was a "silent period" of longer or shorter duration. If, then, there be an absence of the characteristics of enteric fever —of those which make it a certainty—(although, of course, there *may* be no rose rash, or diarrhœa, or ulceration in the progress of a fatal case of enteric fever), is there anything in this case which is inconsistent with traumatic meningitis? The intestinal catarrh and tumefaction of Peyer's patches would be presumptive of enteric fever, if taken apart from other circumstances, but when it is added that the deceased had administered to him strong purgatives (composed of calomel, scammony, and gamboge) by Dr. Seaborne, on account of constipation, and afterwards calomel again, with the effect of diarrhœa for two days, it is not surprising that such a condition existed. Niemeyer was referred to in corroboration of this. It is also a well-known fact, that in traumatic or inflammatory fever the same occurs, the intestinal mucous membrane presenting the "appearance of acute catarrhal inflammation, with some swelling of the lymphatic structures, if there has been diarrhœa" in the course of the disease. I am quoting from Dr. Green's Pathology and Morbid Anatomy, second edition, page 226. Further on are mentioned some interesting results of Dr. Burdon-Sanderson's observations on the subject, which show that the lesion setting up the inflammatory process need not necessarily communicate with the external air in order to give rise to a septicæmia. This is the explanation I should have given of the intestinal catarrh, though no doubt it was aggravated by the purgatives.

The intermission of a day or two, as shown by Mr. Erichsen, is a very frequent occurrence in cases of traumatic encephalitis.

It was unfortunate that the spleen was not weighed at the post-mortem, but as it was not judged by anyone to be beyond the limits it might reach in health, it does not affect the issue, though it also becomes enlarged sometimes in traumatic fever.

The medical evidence in this case extended over three whole days, and resulted in a verdict for the plaintiff, and I cannot but think that if the medical profession were in possession of all the evidence they would come to the conclusion that it was a just and true one, and that the jury have deserved the praise accorded another jury by yourself in The Lancet of July 31st, for their discrimination—that "through juries science often speaks." It is no doubt a pity that the case was ever allowed to go to trial, and that the railway company was advised to show such uncommendable alacrity in making intricate a case which, standing on its own merits, was tolerably clear from the commencement. Would it not have been a suitable dispute for arbitration by competent judges?

I am, Sir, yours faithfully,

Doncaster, Aug. 13th, 1875. J. B. Withington.

P.S. Some blame was attached to the medical attendants of the deceased for raising an objection when the medical officer of the company wished to remove the affected portion of intestine for examination by an expert—after the brain and the membranes had been so destroyed as to be unfit for a similar purpose. Doubtless it would have been better had the objection not been made, but should not the membranes have been treated in the same way?

It would be interesting to know whether the iliac pain and tympanites Mr. Fox noticed on his visit was before or after the administration of the strong purgatives, and also whether it would have been more strictly in accordance with professional usage to have visited the patient in conjunction with his own medical attendant?

CHLOROFORM OR ETHER.

To the Editor of The Lancet.

Sir,—I have read (in your impression of August 7th) with great pleasure the interesting and practical letters of Messrs. George Pollock, R. Brudenell Carter, and J. Warrington Haward, and am glad to avail myself of the opportunity of recording my personal experience of the relative merits of chloroform and ether as anæsthetics. My observations have not been anything like so colossal in their proportions as Mr. Carter's, but inasmuch as they have been made in connexion with a different class of cases, they may be of interest to those travelling the same professional track as myself.

I have used ether and chloroform in about an equal number of cases during the last two years. Those in which ether has most favourably commended itself to my attention are the cases in which it is often necessary to continue the anæsthetic for a considerable length of time, such, for instance, as ovariotomy, abdominal sections, operations upon and in the region of the uterus, vagina, perineum, rectum, &c. It is not a very uncommon occurrence to meet with instances in which continuous anæsthesia is necessary (from various causes) for an hour, an hour and a half, or even two hours under exceptional circumstances. In such cases ether is a most valuable and reliable anæsthetic. Once well under its influence the patient is perfectly quiet and free from the various indications of pain which are, not uncommonly, observed when chloroform is inhaled, as well as from the sudden attacks of spasmodic cough so often met with in chloroform administrations; these spasmodic troubles are most unpleasant to the operator. Reaction after ether, when long continued, is both rapid and well marked. I may here state another most important fact—viz., that I have never known vomiting to occur after ether inhalation. This is a point of vital importance to those having much to do with ovariotomy, plastic operations about the bladder, perineum, &c. I well remember a case, ten years ago, which was the occasion of the greatest possible anxiety. Vomiting of a very urgent character came on during the night following the operation. So severe and prolonged were the spasmodic contractions that the sutures gave way, and the abdominal contents were forced out of the cavity. The patient had again to be placed under chloroform while they were returned, and the wound again secured. The lady recovered ultimately, but the accident was a most unpleasant and dangerous one.

The failures in plastic operations about the bladder and perineum from the same cause (vomiting) have, in my experience, been more numerous than from all other causes put together. If this is the experience of practical men, how highly ought they to appreciate so valuable an anæsthetic as ether.

There is a certain small percentage of cases met with from time to time to which chloroform appears to be altogether unsuited, and in which, if pressed, it would be, as far as I have had an opportunity of judging, incompatible with the life of the patient. Three such cases have come under my personal observation during the present year. The first was a lady aged twenty-six, suffering from a very obscure and painful abdominal tumour. A thorough and careful examination, under chloroform, was deemed necessary to complete the diagnosis. The second was that of a young lady aged twenty-one, who had been suffering from continuous uterine hæmorrhage for four months, which had greatly reduced her strength and impaired her general health. This lady, being unmarried, strongly objected to a vaginal examination, and chloroform was necessary to overcome the objections of herself and friends. The third was that of a married lady aged thirty-eight years, suffering from an old-standing fistula in ano. Although these three ladies differed so much in age and class, as well as in the diseases from which they severally suffered, yet the effects of chloroform upon them appeared to be identical. After chloroform had been inhaled quietly for a short time, sudden and distressing symptoms of suffocation occurred, accompanied with severe struggling and spasmodic pains about the region of the heart of a most alarming character. So great and urgent were the general symptoms, that for some minutes there were considerable doubts as to the ultimate safety of the first and third cases. In all the contemplated operations had to be abandoned for the time. The first two cases, however, took ether, preceded by the "gas," two days after the unsuccessful attempts with chloroform, with the greatest possible ease, comfort, and safety, while the third was so thoroughly frightened by her chloroform experience that nothing could induce her to try the ether; she preferred the pain of the operation to what she called "the horrors of chloroform." These, I submit, are types of the class of cases which fall victims to chloroform inhalation when pressed beyond a given point. I feel certain that two of the three patients mentioned above would have died if the chloroform had been continued.

There is another important class of cases in which ether is entitled to supremacy over chloroform—namely, those of extreme nervous irritability, whether the result of constitutional peculiarity, of disease, or of alcoholic absorption. It is a well-known fact that such persons will usually absorb an extraordinary quantity of chloroform, which in some cases appears to accumulate in the system. Suddenly, when all seems to be going on satisfactorily, the head falls to one side, the face becomes deadly pale, the lower jaw drops, the eyelids are widely separated, while the eyes are fixed and staring, giving to the patient the appearance of death, respiration being for the time arrested, and the heart's movements reduced to a feeble flutter. I have, unfortunately, had more than one opportunity of observing such cases. By active artificial respiration, &c., such patients usually recover, but they are not by any means pleasant objects for contemplation.

Since writing the above I have read Mr. Hodges' letter on the "relative *ultimate* safety of chloroform and ether" (THE LANCET, August 14th). It is suggested that the inhalation of ether is more frequently the cause of bronchial irritation than chloroform. My experience would lead me to the confirmation of this view under certain circumstances—viz., where ether is given *directly* and in *large* doses it will be followed by a certain percentage of cases of bronchial irritation, leading to troublesome bronchitis. But this is not the case, as far as I have had an opportunity of observing, where the ether is *preceded* by the nitrous oxide gas.

I must apologise for this long letter, but the importance of the question at issue must be my excuse.

I am, Sir, your obedient servant,

Chester-square, S.W., August, 1875. THOMAS CHAMBERS.

THERE has been an outbreak of foot-and-mouth disease in the neighbourhood of Thurles, Tipperary, but a considerable abatement in the malady has lately taken place. A good deal of sickness, however, prevails among children in the locality, which is supposed to arise from the deleterious effects of drinking milk from cows affected with the disease.

BIRMINGHAM.

(*From our own Correspondent.*)

SMALL-POX at last seems to be dying out; only four new cases being reported for the week ending August 7th, while no deaths from the disease have taken place, and only twenty-nine patients remain in the special hospital. Had equally good means of isolation existed at the outbreak of the epidemic in 1871, there would not, probably, have been 7699 reported cases and 1269 deaths. The sad but convincing lesson has taught our sanitary authorities the importance of endeavouring to stamp out the disease in future by efficient vaccination, early removal and isolation of all cases, and treatment by a special medical officer in a detached hospital. Other sanitary improvements are about to be undertaken by the Corporation under the Artisans' Dwellings Act, in the removal of some of the wretched hovels now occupied by the working classes, and the substitution of new modern buildings, with good approaches, and suitable drainage and water-supply. The deaths for the past quarter have been, according to Dr. Hill's recently issued report, at the rate of 24·30 per 1000, a slight increase of the rate over the corresponding period of last year, but rather due to the prevalence of chest and brain diseases than to those of a zymotic type.

The new fever wards opened in May have not been much used at present; only eleven cases were admitted up to the end of June, but all of these did well. As the advantages of the hospital become better known, no doubt parents will be more ready to send their children to it. Typhoid fever is still present, though it is not of a severe type.

The Birmingham already overcrowded workhouse is to be extended, and an additional resident medical officer appointed; such an officer ought to have been elected long ago, for the work has for years been greater than any one surgeon could perform thoroughly.

The Committee of the Children's Hospital have wisely determined to cease putting infectious cases in the present in-patient wards, and to build two detached infectious wards, each to contain ten beds, also a new mortuary at a greater distance than the present one from the main building.

Walsall is going to make a special effort on the 28th inst., by means of simultaneous collections in all the manufactories and workships, to increase and further develop the cottage hospital. A new wing is wanted to accommodate serious accidents and burns, and this will cost about £1000—a comparatively small sum for such a purpose, and one which ought to be raised in so wealthy and populous a place as Walsall on any one Saturday in the year without the slightest difficulty.

Lord Lyttelton presided at the annual meeting of the Governors of the Birmingham and Midland Eye Hospital, when a very gratifying report was presented; 800 in-patients and 7626 out-patients were treated during the year, as against 658 and 7230 respectively during the preceding year, and the reserve fund had increased from £1644 to £2329. A larger and more commodious building was suggested, but no decision was come to as to removing the hospital from its present central and very convenient site.

Dr. Ballard has again been giving trouble to the sanitary board of another of the great "Black Country" towns by one of his outspoken reports. Wednesbury, however, is spoken of somewhat more favourably than Oldbury or Sedgley, in that its streets are better kept, and that its water-supply is more ample, only 11·8 per cent. of the houses being unsupplied with waterworks water. Still the death-rate is high, the sewers are miserably bad and insufficient, and "description could not impart a notion as to the terribly unwholesome condition of some of the courts and of the habitations in them."

Mr. F. G. Hamilton, who has for the past twelve months been performing the duties of house-surgeon at the Queen's Hospital, has been elected senior house-surgeon to the Royal Free Hospital, London.

There have recently been two successful cases of amputation at the hip-joint in the Children's Hospital. In one case, where the operation was performed for extensive necrosis in a boy aged twelve, there was a rapid recovery; but in the other, a girl aged six, convalescence was protracted. Antero-posterior flaps were made in each case; no tourniquet was used, the vessels being compressed by the thumb, and yet very little hæmorrhage occurred. Under the care of Mr. Elkington and Mr. Thomas, there have also been two excisions of the hip-joint, which seem likely to do well.

At the Queen's Hospital Mr. West performed ovariotomy on a woman aged thirty-eight, who had been married seventeen years, and was the mother of eleven children. The cyst was multilocular, and contained 300 ounces of yellow albuminous fluid, in which floated a great quantity of cholesterine crystals. A small incision was made, and the pedicle fixed with Wells's cramp. On the fourth day the superficial, and on the seventh day the deep, silver sutures were removed, and the patient is free from all symptoms of peritonitis, and is likely to make a good recovery.

Mr. Furneaux Jordan lately had under treatment a man aged thirty-four, the palm of whose hand was lacerated by machinery, and who, on the eighth day after the accident, showed signs of tetanus. The wound was at first poulticed and then dressed with terebene. Chloral hydrate in thirty-grain doses, and subsequently bromide of potassium, were administered with excellent effects, for the tetanic spasms ceased, and the patient was, at the expiration of a month, on the high road to recovery.

Birmingham, August, 1875.

PARIS.

(*From our own Correspondent.*)

Professor Wurtz, Dean of the Paris School of Medicine, having been appointed to the vacant chair of Chemistry at the Faculty of Sciences, will necessarily be obliged to send in his resignation as Dean of the Paris Faculty. On account of the difficulty, however, which is experienced in finding a successor to him, his resignation has been withheld until the reopening of the School in November next. The appointment will very likely be given to M. Sappey, Professor of Anatomy, or M. Gavarret, Professor of Natural Philosophy. All the professors of clinical medicine or surgery are exceedingly reluctant to accept the post of dean, which would take up much of their time, and materially interfere with their professional and nosocomial pursuits.

Active preparations are being made for the forthcoming session of the French Association for the Advancement of Science, which is to take place at Nantes on the 27th, 28th, and 29th inst. The meeting promises to be as successful as those previously held at Lyons and at Lille. It will include many pleasant scientific excursions into Brittany. The medical section bids fair to be highly active and well represented. Amongst the medical and scientific notabilities who have promised to be present on the occasion may be noticed the names of Dumas, the celebrated chemist; Claude Bernard; Wurtz; Professors Baillon, Broca, Verneuil; Marey, of the Collége de France; Lancereaux and Pozzi, of the Paris School of Medicine; Bertillon, Gallard, Pouchet, de Ranse, &c., of Paris; Professors Courty and Béchamp, of Montpellier; Ollier, of Lyons; Leudet, of Rouen; Azam, of Bordeaux, &c. &c. Any information required on the subject of the meeting may be obtained by writing to the secretary, 76, Rue de Rennes, Paris.

It is said that the new Minister of Public Instruction has decided on the adoption of a hygienic measure of reform as regards the dress of the schoolboys in the Lyceums or Government schools. The youths, instead of wearing the present kind of rather tight uniform frock-coat, buttoning up closely in front, would have a loose woollen jacket, allowing greater freedom of movements and fuller expansion of the chest. There is no doubt that the proposed reform would be excellent from a sanitary point of view.

The Municipal Council of Paris is now considering a report on the contemplated rebuilding of the dissecting-rooms of the Ecole Pratique and of the Clinique d'Accouchement, of the urgency of which all who have visited the precincts are fully aware.

According to an article published by the *Pungolo* of Milan, the cremation of a dead body, that of a Chevalier Keller, has been authorised and effected in that city in the presence of several distinguished advocates of incineration, amongst whom were M. Palasciano, of Naples; Professor Coletti, of Padua; Dujardin, of Genoa; and Messato, of Naples.

The heat is at present very severe, and several cases of sunstroke are daily registered. In the provinces the heat has been equally intense, and Professor Daubree, of the Paris Museum, was very nearly killed by falling in one of hollows of the Auvergne mountains under the influence of sunstroke.

In the last list of nomination of Knights of the Legion of Honour figure the names of some professional brethren for the distinguished services which they rendered during the inundations at Toulouse and Agen. Dr. Bonnemaison, head physician, and Nelson Batul, head surgeon of the Toulouse Hôtel Dieu, have been especially singled out. The name of Sœur Penin, the worthy Lady Superior of the same hospital, who, by her great energy, contributed to save so many lives, must also be mentioned with the preceding, as having been the object of the same distinction.

The distribution of prizes has just taken place at the celebrated School for the Deaf and Dumb, founded by the Abbé de l'Epée. The ceremony was presided over by M. Rihouet, Councillor of State, and as he delivered his address one of the professors of the establishment conveyed it to the pupils by means of gesture and mimicry. More than 250 scholars performed afterwards a series of military exercises, going through various manœuvres, which were commanded and executed by means of signs as quickly as if by verbal orders.

Paris, August 18th, 1875.

Medical News.

Apothecaries' Hall. — The following gentlemen passed their examination in the Science and Practice of Medicine and received certificates to practise on Aug. 12th:—

Price, Arthur, Surrey Villas, Thornton-heath, Croydon.
Stephens, Charles, Upper Parliament-street, Liverpool.

The following gentlemen passed the Primary Professional Examination on the same day:—

Bain, David Stuart Erskine, Charing-cross Hospital.
Todd, John, University College.

The Library of the Royal Medical and Chirurgical Society was closed on Monday last, the 16th instant, and will be reopened on Thursday, September 16th.

Dr. John Lowe has been placed on the Commission of the Peace for King's Lynn, and Mr. John L. Williams, M.R.C.S. Eng., for Carmarthen.

Alderman Wm. Groom, J.P., public vaccinator for the first district of the Wisbech Union, has been awarded the first Government grant of £18 4*s.* for successful and efficient vaccination.

The ship "Bremen," of Liverpool, is reported to have just put in to San Francisco with every one on board, passengers and crew, more or less ill with scurvy. Sixteen persons died on the voyage, three while within sight of port.

Bequests, &c., to Medical Charities.—Mr. James D. S. Douglas, of Chilston-park, Maidstone, has bequeathed £200 each to the West Kent Hospital and the Ophthalmic Hospital, Maidstone. Mr. Thomas Osborn has given £100 to the Northampton General Infirmary.

Medical Appointments.

Alcock, J., M.R.C.S.E., has been appointed Public Vaccinator for the Parish of Burslem, Staffordshire.

Archer, E. G., M.R.C.S.E., has been appointed Medical Officer and Public Vaccinator for the No. 5 District of the Guiltcross Union, vice Farrington, resigned.

Ashby, H., M.B., has been appointed Demonstrator of Anatomy at the Royal Infirmary School of Medicine, Liverpool, vice Harris, resigned.

Baines, E. C. A., M.R.C.S.E., has been appointed Medical Officer and Public Vaccinator for the Nettlebed District of the Henley Union, vice Munro, resigned.

Barker, A. E. J., L.R.C.S.I., has been appointed an Assistant-Surgeon to University College Hospital.

Beck, M., F.R.C.S.E., has been appointed Teacher of Operative Surgery at University College, vice Heath, resigned, on being appointed Holme Professor of Clinical Surgery.

Bullmore, W. K., M.D., M.R.C.S.E., has been appointed Medical Officer of Health for the Falmouth Parish Urban Sanitary District: £20 per annum.

Conolly, Rowley, M.R.C.S.E., has been appointed Surgeon in Charge of the European Residents in River Brass, West Coast of Africa, vice Stanmore, whose term of service has expired.

Curwen, C., M.R.C.S.E., has been appointed a Junior House-Surgeon to the Royal Free Hospital, vice Griffiths, resigned.

Davies, H. H., M.R.C.S.E., Medical Officer for the Llandyssul District of the Newcastle-in-Emlyn Union, has been appointed also Public Vaccinator; also Medical Officer of Health for the Llandyssul Sub-district of the Newcastle-in-Emlyn Rural Sanitary District, vice Jones, deceased.

Dunlop, W. M., M.B., C.M., has been appointed Surgeon to the Woodbridge Court of the Ancient Order of Foresters, Suffolk.

Fearnley, W., L.R.C.S.Ed., has been appointed Medical Officer for the Parish of Lerwick and Gulberwick, Shetland, vice Macdonald, resigned.

Hamilton, F. G., M.R.C.S.E., has been appointed Senior House-Surgeon to the Royal Free Hospital, vice Powell, resigned.

Hart, Dr. W. H., has been appointed Medical Officer, Public Vaccinator, and Registrar of Births and Deaths, for the Tullow Dispensary District of the Carlow Union, vice Burnett, deceased.

Hayman, F. D., M.R.C.S.E., has been appointed House-Surgeon to the Metropolitan Free Hospital, Devonshire-square, vice Gallimore, resigned.

Hincks, T. S. H., M.B., C.M., has been appointed Medical Officer and Public Vaccinator for the Herefordshire District of the Hay Union, vice Smith, resigned.

Hodson, H. A., M.R.C.S.E., has been appointed a Junior House-Surgeon to the Royal Free Hospital, vice Hayes, resigned.

Lewis, Mr. T., has been appointed House-Apothecary to the Bridgwater Infirmary, vice Smith, resigned.

M'Aldowie, A. M., M.B., C.M., has been appointed House-Surgeon to the Royal Surrey County Hospital, Guildford, vice Birch, resigned.

Marshall, A., M.D., L.F.P. & S. Glas., has been appointed Medical Officer to the Ayrshire Friendly Sick Society, Kilmarnock, for 1875–76.

Nally, W. J., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer, Public Vaccinator, and Registrar of Births &c., for the Kinwarra Dispensary District of the Gort Union, Co. Galway, vice Hynes, resigned, and since deceased.

Nolan, J. J., L.K.Q.C.P.I., L.R.C.S.I., has been appointed Medical Officer to the Tullow Fever Hospital, vice Burnett, deceased.

O'Kelly, R. A., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Resident Medical Officer at the Limerick Union Workhouse.

Parsons, F. J., L.R.C.P.Ed., M.R.C.S.E., has been appointed Medical Officer to the Royal Humane Society for Portland.

Petit, J., L.K.Q.C.P.I., L.M., L.R.C.S.I., has been appointed Resident Superintendent of the Donegal Lunatic Asylum, Letterkenny, vice Merrick, appointed to the Antrim Lunatic Asylum, Belfast.

Poore, G. V., M.D., M.R.C.P.L., has been appointed an Assistant-Physician to University College Hospital.

Roe, C., L.R.C.S.I., has been appointed Superintendent and House-Surgeon to the Chalmers' Hospital, Banff, vice Donald, resigned.

Smith, P., M.R.C.S.E., has been appointed Ophthalmic Surgeon to the Queen's Hospital, Birmingham.

Taylor, J. M., L.R.C.P.L., M.R.C.S.E., has been appointed Medical Officer for the Burslem South-West District of the Wolstanton and Burslem Union, vice Goddard, resigned.

Walby, T., L.R.C.P.Ed., M.R.C.S.E., has been appointed Assistant Medical Officer to the No. 2, or North District of the Ladies' Charity and Lying-in Hospital, Liverpool, vice Pughe, transferred to No. 8.

Births, Marriages, and Deaths.

BIRTHS.

Campbell.—On the 13th inst., at Wellesley-terrace, Prince's-park, Liverpool, the wife of Wm. Macfie Campbell, M.D., of a daughter.

Duncan.—On the 12th inst., at Buckingham-palace-road, the wife of H. M. Duncan, M.D., of a son.

Snagg.—On the 13th ult., at St. Vincent, West Indies, the wife of Richard Snagg, M.R.C S.E., L.R.C.P.Ed., of a son.

Ward.—On the 15th inst., at Saltburn, Twickenham-common, the wife of Martindale C. Ward, M.D., of a daughter.

Weber.—On the 13th inst., at Grosvenor-street, the wife of Hermann Weber, M.D., of a son.

MARRIAGES.

Pringle—Smith.—On the 17th inst., at Nolton Chapel-of-Ease, Bridgend, Henry Turnbull Pringle, M.D., Medical Superintendent of the Glamorgan County Asylum, to Jessie Isabella, only daughter of the late Thomas George Smith, Esq., of Bridgend, Glamorganshire.

Ross—Smith.—On the 10th inst., at St. Peter's, Brighton, Alexander Clarke Ross, M.D., Surgeon-Major Army, to Sarah Ann Watts, daughter of the late George Smith, Esq.

DEATHS.

Anniss.—On the 6th inst., at Albert-road, Tamar, Devonshire, Wm. James Anniss, L.F.P. & S. Glas., aged 38.

Digan.—On the 9th inst., at Plymouth, Patrick Digan, M.D., R.N., aged 55.

Inglis.—On the 11th inst., at Worcester, Florence, wife of Alex. Inglis, M.D.

Jefferiss.—On the 8th inst., at Dalkeith, Robt. R. Jefferiss, M.R.C.S.E., aged 74.

Johnson.—On the 14th inst., at Southwick-street, Hyde-park, Cavendish Johnson, M.R.C.S.E., Surgeon-Major Indian Army (retired list).

Ker.—On the 7th inst., at Dumfries, John A. Ker, M.D.

Rowley.—On the 10th inst., at Milton-next-Sittingbourne, Kent, John Rowley, M.R.C.S.E., aged 63.

Snow.—On the 16th inst., at Lincoln, James Snow, F.R.C.S., in his 95th year.

Ward.—On the 10th inst., at Penistone, Yorkshire, John Ward, M.R.C.S.E., aged 60.

[N.B.—*A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*]

Notes, Short Comments, and Answers to Correspondents.

Silent Paving.

The Whitechapel District Board of Works have gracefully responded to the application of the authorities of the London Hospital for a silent paving material to be laid down in the roadway fronting and at the eastern end of that institution, by passing a resolution that East Mount-street be paved with wood. The boon which will be thus secured to sufferers in the hospital in the shape of increased quiet will necessarily be of incalculable value, and cannot but be heartily appreciated by the patients, especially by those in whom the nervous system is more directly affected.

Enquirer.—An excellent little book on the subject (Mushrooms) has been written by Mr. Cook.

The paper of *Mr. Robert Lawson* (Wakefield) shall be immediately published.

Case of Double Facial Paralysis and Deafness in a Patient suffering from Syphilis.

To the Editor of The Lancet.

Sir,—The following case is, I think, of sufficient interest to warrant its publication.

R. W——, male, aged thirty-five years, tall, spare, and not over temperate in habits, just before leaving America for England, became infected with syphilis. Three weeks after inoculation a small indurated chancre made its appearance at the frænum of the prepuce, and was followed in a few days by enlargement of the inguinal glands of the right side, and in eleven days by sore-throat and a macular eruption about the face and neck. No treatment was adopted during the voyage; but upon admission to the Lock Hospital of the Liverpool Workhouse on the 17th December, 1873, he was given a solution containing five grains of iodide of potassium, with one drachm of solution of perchloride of mercury, three times a day. Symptoms of salivation manifesting themselves on the 1st January, 1874, the mixture was discontinued. At this time he complained of pains about the body, more especially of the right side of the head and right shoulder, which became intensified at night. There was slight nodulation of the right clavicle and tenderness down the spine, with startings of both legs, and a constant singing in the ears. On the 2nd of January the patient became aware of inability to close the right eye, and from this date symptoms of *right* facial paralysis developed themselves. On the 28th of the same month the left side of the face became similarly affected, and by the 31st the whole face had become a blank expressionless mask. He was unable to close either eye, and when he tried to whistle the breath came out between the lips in a horizontal line from one corner of the mouth to the other. The hearing was equally good in both ears, and sensation perfectly natural on both sides of the face. Though no more mercury had been given, symptoms of salivation still persisted. As he complained of great pain in the brows and head, with restlessness and inability to sleep, he was given bromide and iodide of potassium. By the 10th of February the symptoms of intense restlessness, sleeplessness, and pain had become relieved, and the left side of the face had resumed some of its natural appearance, the muscles of that side putting on a tremulous involuntary motion. The hearing on the right side now began to get dull, and, all symptoms of salivation having for some time passed away, the patient was given one mercurial vapour bath a day, with the result of the reappearance of salivation on the third day. On Feb. 24th there was great prostration of strength and severe pain in the right ear, in which were heard loud sounds as of rushing water. Upon examination with the ophthalmoscope, the optic discs were seen to present a fringe of vessels, forming a vascular ring, in the centre and round the outside of which the parts were pale. This vascular ring was darker in the left than in the right eye. Upon applying glycerine to the tongue, it was tasted distinctly at the right edge, but not at all at the left edge. Faradisation of the muscles produced muscular spasm on both sides. On March 10th the hearing on the left side began to be affected as the right was a month previously. One grain of mercury with chalk and ten grains of compound ipecacuanha powder were now given at night, but, the gums becoming tender, had soon to be discontinued. On April 4th, in order to test the patient's susceptibility to the action of mercury, half a grain of mercury with chalk was ordered to be given twice a day; but on the third day, the specific action of the drug manifesting itself, and erysipelas showing itself on the left side of the head and face, it was discontinued. The erysipelas extending over the whole of the head and face, a mixture of iodide of potassium, iron, and ammonia was given; and on the 9th of May, after the erysipelas had entirely passed away, thirty-grain doses of iodide of potassium alone were administered, and increased till as much as sixty grains three times a day were taken. Under this treatment the patient's health steadily improved, and he became quite stout and strong; the deafness of the right ear passed away, and the left side of the face began to assume a more mobile and natural appearance, the right side, however, continuing paralysed. At the end of July the left side of the face presented its natural appearance. There was, however, complete deafness on that side. The right side of the face still showed evidences of paralysis, though slight. There was a scaly papular eruption on the left arm, and the right inguinal and left cervical glands were slightly indurated.

As the patient ate well, slept well, and felt well, he considered himself quite well, and, against advice, persisted in discontinuing treatment and resuming his seafaring career.

I remain, Sir, yours &c.,
J. H. Barnes,
Late Surgeon to the Liverpool Workhouse Infirmary.
August, 1875.

Honorary Secretary.—The bill is a most discreditable production. If anything could add to the discreditableness, it would be that the writer should be in good practice, and not able to fall back on the common excuse of impecuniosity. The Medical Society in question should express and record in plain terms its opinion.

Mrs. Duckett.—It does not constitute a disqualification.

Human Styes.

A week or two ago we referred to a proposal which had been made, under the new Artisans' Dwellings Act, to improve a foul spot lying to the north of Holborn, and bounded on the west by Gray's-inn-lane. Another area, in Whitechapel, of even worse character, is about to receive the deserved attention of the Metropolitan Board of Works. In this area there wallow 2369 people, each person having, according to Mr. Liddle's estimate, only on an average 8·2 square yards, and the rate of mortality in the locality was, in 1873, 38·4 per 1000. The description by Mr. Liddle of some of the courts and alleys in this region is simply appalling, and serves to show the urgency of the need of the legislation which Mr. Cross's Act has to some extent supplied.

Dr. Muscroft (Pontefract) is thanked for his letter.

The Death under Chloroform at Quarry Bank.

To the Editor of The Lancet.

Sir,—I must apologise for again troubling you with a letter upon the above subject; but Mr. Ashmead's letter in last Saturday's Lancet, in which he tries to controvert my statements, compels me once more to deal with a few facts relating to the case.

1. Let me say that since I last wrote I have obtained from the coroner an official copy of the evidence given at the inquest, and shall therefore, in any allusion I may make to Mr. Ashmead's evidence, quote word for word from that document.

2. In Mr. Ashmead's letter to you he says, "the condition of the heart's cavities indicated syncope, yet the bloody froth issuing from the mouth and nostrils, and the intense violet tint of the face, as well as the condition of the lungs, pointed towards death from suffocation."

There can be no doubt whatever that the appearance of the face was entirely post-mortem, the result of decomposition—not surprising when the state of the atmosphere and the time of year are taken into consideration, together with the fact that the subject had been dead three days. Mr. Ashmead himself, in his evidence, confirms this fact; for he says "the skin had commenced peeling off the arms in consequence of decomposition."

3. The point in his letter, however, that I wish most particularly to draw attention to is the following: "The statement that the abdomen contained three pints of pus is perfectly Munchausen in character. In the hurry of cross-examination I overstated the amount, which was, in reality, not more than three ounces diffused about." But this is in direct opposition to Mr. Ashmead's own statement as given in evidence to the coroner, in which he says: On examining the abdomen, a *large quantity* of matter—pus—was found there." Afterwards, in cross-examination, he stated: "There was more than a pint of matter collected in the abdomen."

With regard to my statement of the case in The Lancet of August 7th, I simply said that Mr. Ashmead did not in my presence make any examination as to the amount of pus in the cavity, and that I should certainly think, from appearances, that there must have been at least three pints of pus.

Mr. Ashmead also stated before the coroner that he detected chloroform in the tissues. I am not aware of any known process by which it could be detected three days after death.

In urging upon the police in the first instance the necessity of an inquest, I did so believing it to be a duty incumbent upon me to have elucidated a matter of so much importance to the public and of such interest to the profession.

With these remarks I leave you and the readers of The Lancet to judge who deserves the name of "Munchausen."

I am, Sir, yours truly,
August, 1875. Hugh R. Ker.

P.S.—One of the leading London pathologists taught me, when a student, never to rely on any test for consolidated lung, save that of throwing portions of it into water. This test was not applied at the post-mortem.

Danger of "Wakes."

At Haslingden an outbreak of small-pox is reported by the medical officer of Health, Dr. Harrison, to have originated as follows:—Three weeks ago an Irish haymaker took the disease and died. The rural sanitary authority put out placards warning people to keep away from the infected dwelling, but the Irish persisted in visiting it. When the man died the medical officer appointed a watchman, who stayed until midnight, and then left. After this the Irish entered, and held a wake over the body. Soon after the wakers were stricken, and two died, whose remains it was found necessary to bury within twelve hours. There are now four persons suffering from small-pox in the village, and whose infection is traced to the disastrous and stupid custom practised by the Irish.

A. M.—The law has not prescribed any rules on the subject.

Unqualified Medical Practitioners and the Registration of Deaths.

To the Editor of The Lancet.

Sir,—In corroboration of what your correspondent states in your last, I may add that, as a result partly of registrars not being supplied with a copy of the Medical Register, one of these gentlemen in my neighbourhood stated it was not his business to test the validity of any certificate transmitted to him; that if a certificate, signed, and purporting to be from a registered practitioner, came to him, he did not think of questioning it. He has, however, since, on receiving a certificate from an unqualified person on blank paper (not official), gone to the friends and asked them if they were satisfied that their child or relative died of the complaint so stated!

Another registrar in an adjoining parish, on getting a certificate signed by a medical man who did not see the case from first to last, when this was reported to him, did make inquiries, and finding this to be irregular, to say the least, reported the same to the superintendent registrar of the district, who told him it was no business of his, and if some other medical man in the neighbourhood chose to take it up he could do so.

These are two instances out of many under my observation, and which only go to prove what a sham this registration of deaths is as at present carried out.

Yours &c.,
August 17th, 1875. Justitia.

Ovarian Compression in Fits of Hysteria.

Dr. Charcot, of La Salpêtrière, believes that in the majority of hysterical fits there exists an *aura* which takes its starting-point in one or other of the ovaries, and sometimes in both. Therefore, in order to arrest immediately a fit of hysteria, it suffices to exert strong pressure over the ovary where the aura is seated. In his hospital wards he has often shown the effectiveness of the method, alternately checking an hysterical fit or allowing it to go on by applying or removing compression. In order to exert protracted pressure he makes use of a sort of tourniquet. In manual compression, the fingers are pushed down behind the pubis, where the artery can be felt distinctly beating.

Chiron.—The letter is too long for insertion. We shall consider the question.

Army Medical Department.

To the Editor of The Lancet.

Sir,—In a leading article of a contemporary of the 24th ult., commenting on some Army Medical Regulations recently issued, there are so many erroneous statements that one feels constrained to notice them, as they may give rise to much misconception outside the department. A contrast is drawn between these Regulations and the book of Medical Regulations issued in 1859, and the completeness of the latter as compared with the former is dilated on. All the criticism, however, is uselessly expended, as it is based on the utterly wrong assumption that the rules just issued constitute the new code in its entirety. It is well known that they form only a very small portion of it, dealing merely with four subjects.

The part of the paragraph referring to attendance on parades, which has been taken as an illustration of slovenly, unintelligible composition, and contradictory statements, is, I find, an extract from the Queen's Regulations, which, no doubt, had to be quoted as the authority on the matter; and to instance, if indeed necessary, a parallel case, of the significance in which the word "attendance" is employed, everyone in the service is aware that a medical officer is said to attend rifle firing, although he may not be actually on the ground, but only within call.

The regulations with regard to the distribution of the sick, which is adduced as another example of contradiction, were practically in force in every consolidated regimental hospital—that is, the sick were grouped regimentally, and treated by the regimental medical officers; but certain wards were appropriated for sick prisoners, cases of infectious disease, ophthalmic cases, lunatics, &c., and in these wards patients were treated irrespective of corps distinction. The duty of thus segregating certain cases, and determining the wards in which they are to be placed, now devolves on the medical officer in charge, and therefore he is given the power detailed in paragraph 3, page 9. One fails to perceive wherein the inconsistency exists.

It is asked, what about those medical officers who live at a distance from the station hospital when the sick are to be treated by the medical officer attached to corps? It is well known that a great outcry was raised when medical officers attached to corps were debarred from hospital practice. Now that they are to attend to the sick of their corps "as far as practicable" in the station hospital, an objection is at once raised on the score of a contingency that may occasionally arise, and which it is the duty of the administrative medical officer of the district to provide for.

The remark made with regard to those living within the prescribed radius is simply a slur on medical officers who ought to be acquainted with the army circular, in which the distance is laid down. No doubt the extent of the prescribed radius will be mentioned in the new code in its proper place.

With regard to paragraph 7, page 6, in which it is stated that non-commissioned officers and men are not to be treated out of hospital, it is merely a quibble to assert that it is contradictory to the preceding, which, on the other hand, plainly shows that it only can refer to patients requiring hospital treatment.

The query is put, How can a medical officer attached to a regiment keep the regimental medical records in barracks when he is to treat the sick of the corps in hospital? The answer is, that there are regimental medical returns and station hospital returns; the former are kept in the barracks, because they are not wanted at the station hospital; and the latter at the hospital, as they are not required in barracks.

In fact, not one of the charges brought against these Regulations has been in any way substantiated; and to show the unfair, one-sided kind of criticism in the article referred to, out of four subjects, two, that would be, I dare say, susceptible of some modification before the new code is issued in its complete form, have been seized upon for unfavourable comment.

In conclusion, I have only to add that where so many blunders have been committed by the writer, one begins to doubt his capacity to judge of the capability of those who have the responsibility of drawing up the new code of Army Medical Regulations.

Your obedient servant,
August, 1875. Fair Play.

Lex.—A registered practitioner cannot legally depute to an unqualified assistant the duty of signing certificates required by law. If our correspondent knows of an instance in which paupers are attended entirely by an unqualified assistant, he should report the facts to the Board of Guardians or the Local Government Board. Such a system is both discreditable and illegal. Friendly Societies have the remedy in their own hands, and may do as they please.

Sigma.—Information as to baths will be found in special works. Our correspondent will judge better than we can of the fee for the surgical service referred to. The other service mentioned was not a professional one.

Discharge of a Calculus from the Umbilicus.

To the Editor of The Lancet.

Sir,—A case somewhat analogous to the second of those related by Mr. Edward C. Anderson in this day's Lancet is given in the "Biennial Retrospect of Medicine, Surgery, &c., for 1871-72," published by the New Sydenham Society, page 279. It is the case of the discharge of a cholestearine calculus, weighing 390 grains, from the umbilicus of a young lady. It was supposed that the calculus had been three years making its way to the surface.

I am, Sir, yours faithfully,
Penzance, Aug. 14th, 1875. A. B. B.

Cookery.

Considering the important part that the skilful preparation of food plays in dietetics, it is to be regretted that the labours of the National Training School of Cookery have not been attended with more success than the published results would seem to imply. Out of 766 pupils who have passed through the school, only three have succeeded in obtaining diplomas as teachers. These numbers are so disproportionate as to suggest some defect in the method of instruction, were it not for the strong testimony that has been borne to the excellence of the lectures given at South Kensington.

Mr. Lawson Tait. — Centralblatt für die Medicinische Wissenschaften, No. 26, 1875.

The Indian Medical Service.

To the Editor of The Lancet.

Sir,—As a regular reader of The Lancet, I have an opportunity of seeing many of the letters and communications written on the subject of the medical services, Naval, British, and Indian, and it is with regret that I observe there is an apparent misunderstanding as to the value of the Indian service, as compared with the others, as a career for the young surgeon. It is a matter for regret, inasmuch as it places us in a false light, and misleads others.

I have no private ends to serve, I may remark, in speaking depreciatingly of the service to which I have the fortune to belong. What I am about to say is mainly intended for the benefit of those students or others who may at the present moment be contemplating entering one of the public services, and who may not have as yet decided which they consider worthy of their choice. I would advise those who have no special reason for selecting the Indian service, to pause ere they do so in preference to entering one of the others, with the new Naval Medical Warrant before their eyes, and the prospect, it is to be hoped, of an early adjustment of the grievances of the officers of the army medical department.

I shall say nothing of the advantages or otherwise of the sister services, inasmuch as students can easily inform themselves thereof at home, but shall confine my remarks to the Indian service, in regard to which such mistaken views frequently prevail amongst students, and teachers, too, for the matter of that, to whom the former so frequently look for advice on the point.

I have an honest wish to represent the Indian medical service in its true colours, even though my doing so may destroy the illusions of some of Dr. Fayrer's audience on the occasion of his recent address at Netley. About this same address the *Indian Medical Gazette* of June 1st remarks: "The address dwells exclusively on the bright side of an Indian career, and the prizes of the service are prominently exhibited. A curtain is drawn on the dark side—unemployed pay, officiating appointments, frequent and expensive moves, not a little favouritism and jobbing, confused administration, depreciation of the value of salaries, increasing expenses of living, bad health, separation from wife and children, domestic troubles and trials." And I would add from myself, though last not least, miserably inadequate pensions on retirement. I ask, in the name of fairness and common sense, why did the address dwell exclusively on the bright side of an Indian career? Is it fair, is it just, considering the weight that would naturally attach to Dr. Fayrer's utterances on the subject, and the degree to which they may influence, if not determine, the career of many who are still *in statu pupillari*, either directly or indirectly through their teachers? If a man were to dwell exclusively on the advantages of service on the West Coast of Africa, and the rapidity of promotion accruing therefrom, I wonder how many of those who accepted his dictum, and acted upon it, would afterwards bless him? Dr. Fayrer's good fortune and success, though, doubtless, no more than he deserves, may at the time have helped him to forget that his career should not by any means be taken as illustrative of that of the average Indian military or civil surgeon.

To return to the points noted in the *Indian Medical Gazette.* The "unemployed pay" rule alluded to is a source of great disappointment and heart-burnings to the young surgeon. From the wording of the rules supplied to him from the India Office, he is led to expect, as I was myself eight years ago, that he is entitled to the employed rate of pay on passing the prescribed examination in one of the languages of the country, and performing duty. But no such thing. It may be years before he is permanently posted to a regiment or civil station, until when he draws the unemployed rate only, plus some acting allowance. The latter is not unfrequently swallowed up in travelling expenses, if the acting appointment be of short duration, or the journey a long or expensive one, as the Indian Government will not allow travelling expenses if the increase in emoluments be never so small. This is no imaginary picture, as a reference to the Army List will show that there are surgeons on the Madras establishment of the season of '69 who have up to the present never been permanently posted to either a military or civil appointment. Officiating appointments involve diminished allowances, uncertainty of tenure, and frequent moves, every one of which latter is more or less expensive.

I shall allow myself to do no more than mention the fact that favouritism, jobbing, and confused administration exist in the Southern Presidency. The depreciation in the value of salaries, however, is a matter of common interest to all; the depreciation in the value of money and ruinous rate of exchange on home, with unfortunately the concurrent increased and increasing expenses of living, are unpleasant facts, and most unquestionably seriously diminish the value of Indian appointments.

The probability of bad or deteriorated health from lengthened residence in the tropics, with the certainty at some time or other of separation from wife and children, are, and have always been, drawbacks to an Indian career; but ought, none the less, be taken into account in estimating the relative value of the different services while there is still a choice.

The pension rules, framed for other days and under different circumstances, are miserably inadequate to enable a man, after a service of twenty-five or thirty years in India, to live in comfort at home, and help to provide for a family, if haply he have such; and the depreciation of the value of salaries and increased expenses of living above alluded to render it simply out of the question for the majority to save sufficient to supplement these pensions to any extent.

I dare say it is known to the Editor of The Lancet, and it ought to be to everyone who contemplates an Indian career, that the medical funds, which formerly formed one of the principal attractions of the service, are no longer available, Government, with cruel parsimony, having debarred all those who entered since 1860 from joining them. These funds, which often enabled a worked-out man to retire by supplementing his pension, have now, as their most miserable representative, the Indian Family Pension Fund of 1873, which, though demanding high donations and subscriptions, gives a wretched pittance to widows and orphans, and lacks altogether the annuity branch, which provided an annuity after a certain number of years' service, as above mentioned. This new Fund is, in the opinion of many, no better, if so good as an insurance on one's life, high though the Indian rates for the latter are.

These, Sir, are some facts connected with this much belauded and eulogised service, which students are encouraged so to enter.

There are other matters which I should much wish to notice, but that I fear I have already trespassed too much on your space, but which may form the subject of a future communication, if you will permit me.

I trust you will give insertion to this in the columns of The Lancet, and that it may be the means of provoking expressions of opinion from other members of the service, and so ventilating our grievances.

I remain, Sir, your obedient servant,
Madras Presidency, June 19th, 1875. Local.

Value of Partnership.

A Constant Subscriber.—Everything depends on circumstances. A good partnership—by which we mean association with a good partner in a sound practice—should be worth two years' purchase; but a bad partnership would be cheaply avoided at the cost of one year's profits.

A. M. D.—We have not received copies of the examination papers referred to by our correspondent. They are published in the departmental blue-book; but it is not our practice to print them in our columns.

Dropsy of the Amnion, requiring the Removal of the Fluid and consequent Induction of Premature Labour.

To the Editor of The Lancet.

Sir,—The following case will, I think, be found sufficiently interesting and rare to warrant its publication.

Mrs. G——, a tall, pale woman, of active habits, and the mother of eight children, two of whom were twins, engaged me to attend her some three months previous to the time expected. She at the same time complained of loss of appetite, weariness, &c.; but her reason for sending for me was that she scarcely passed any urine; it often did not amount to more than three or four ounces in the twenty-four hours; it was intensely acid, and loaded with lithates; no albumen. For some weeks I tried various diuretics, tonics, &c., but without benefit. She steadily got worse, so that about four weeks after I first saw her she had to take to her bed. She now had constant cough, sleeplessness, loss of appetite, and great emaciation, and seemed to be in a very critical condition. On placing my hand on the abdomen, I found it enormously enlarged, and uniformly fluctuating. The girth at umbilicus was forty-two inches. On vaginal examination, the uterus felt like a tightly distended bag of fluid; the os high up, and pointing backwards; cervix entirely obliterated; ballottement very well marked. I requested my friend Mr. Cheesman to see the case with me, and we came to the conclusion that it was one of dropsy of the amnion, and that the membrane should be perforated without delay; but we thought it our duty to urge on the friends the propriety of calling in Mr. Martin Coates, of Salisbury, who came and agreed to what we proposed doing.

The following day I perforated the membrane with a porcupine quill, intending to let the water drain off as slowly as possible. In less than an hour two gallons had been caught, and at least one more had soaked through the bed. Pains came on in about six hours afterwards, and in two hours more she was delivered of a male infant, who feebly gasped once or twice. The placenta came away naturally, and was very small. In all the similar cases I can find recorded it seems to have been extremely large.

I forgot to say that no fœtal heart could be heard, and that on one occasion I distinctly felt, through the abdominal wall, the movements of the child.

The patient made a good recovery, and is now in excellent health.

I remain, Sir, yours truly,
Gillingham, Dorset, August, 1875. T. Woods, L.R.C.P. Lond.

Ancient and Modern Medicine.

To the Editor of The Lancet.

Sir,—In discussing Dr. Warburton Begbie's Address in Medicine, you state that the question he quotes from Sir Wm. Hamilton, "Has the practice of Medicine made a single step since Hippocrates?" was put by the illustrious professor in 1832, and you ask whether, "allowing that Sir William's question was not unreasonable in 1832," there was any justification for Dr. Begbie reviving it in 1875.

Allow me to draw your attention to the fact, which you can easily verify for yourself in one of our public libraries, that the question referred to was not put in 1832, when the original article appeared in the *Edinburgh Review*, but that it appeared for the first time in 1852 in the collection of the Professor's essays, published under the title of "Discussions on Philosophy and Literature," and that it was then contained in a note which was enclosed in square brackets, to signify that it was new matter. This note having naturally given offence to some of the Professor's medical colleagues in the University, another was added in 1853 in the second edition, in which the author strove to justify his position by stating that he had only quoted from high medical authorities, and making further quotations from them to the same effect. It is from these two notes published in 1852 and 1853 respectively that Dr. Begbie has quoted, though probably many readers of the Address would have thought, with you, that he referred to the original article. It seems to me, however, that the fact of Sir Wm. Hamilton's question having first appeared twenty years later than you supposed, fully justifies Dr. Begbie's selection of it as his text, and adds point to your observations as to its ungraciousness.

I am, Sir, your obedient servant,
Fitzroy-square, Aug. 14th, 1875. H. Nelson Hardy.

Injurious Effects of Vegetable Decomposition.

To the Editor of The Lancet.

Sir,—I should feel most grateful to any of your numerous readers who could indicate to me where I am to find information on the injurious effects of vegetable decomposition in the production of fevers and disease generally in any part of the world. Your obedient servant,
Great Marlborough-street, Aug. 6th, 1875. Medicus.

OVERCROWDING IN IRELAND.

A SANITARY officer in the county of Clare reports that he lately found ten human beings in a tottering mud edifice 13 ft. by 7 ft. Seven slept in one bed, and a younger member of the family in a hen-coop. The roof was decayed and riddled with holes, and a dunghill of putrefied matter outside emitted a terrible stench. One child was quite naked. The family are receiving out-door relief. Although the foregoing account depicts a most extreme case of overcrowding, we have no doubt that metropolitan medical officers of health not unfrequently come across parallel cases in some of the courts and alleys which we hope to see improved away in a few months.

EXPENSES OF WITNESSES IN VACCINATION PROSECUTIONS.

THE *Local Government Chronicle* states as follows:—

> "In a case which recently came before the justices at Taunton, a question of some importance was raised with reference to the expenses of prosecutions under the Vaccination Acts. Mr. Goodman was summoned for not having his child vaccinated; and Mr. Trenchard, the clerk to the guardians, conducted the case for the vaccination officer. After submitting evidence as to the failure to comply with the requirements of the statute, Mr. Trenchard said that it was the second time that they had had to bring Mr. Goodman before the justices. On the first occasion they had to issue a process to obtain the fine, and he asked for the full penalty to be imposed. As he considered it hard for the ratepayers to have to pay the costs of himself and the vaccination officer for attending there, he must also ask the Bench to make an order for the professional expenses in the case.—The defendant said that Mr. Trenchard and Mr. Cornish, the vaccination officer, were paid officers of the union, and attended in the discharge of their duties.—Mr. Trenchard replied that he appeared there, not as clerk to the guardians, but as the professional adviser of Mr. Cornish, who would receive what the guardians thought fit for his attendance. Whatever the guardians gave him would come out of the ratepayers' pockets. Their attendance did not come within their ordinary duties; he was simply there as solicitor to the vaccination officer.—Captain Doveton said the Bench had decided to convict in the case, and to inflict the full penalty—20*s.*, 6*s.* costs, and 10*s.* 6*d.* each for the attendance of Mr. Trenchard and the vaccination officer—in all, £2 7*s.*"

ABSTRACT

OF A

Clinical Lecture

ON

A CASE OF SYPHILITIC DISEASE OF THE LIVER,

WITH PECULIAR PHYSICAL SIGNS IN THE ABDOMEN.

BY HENRY THOMPSON, M.D., F.R.C.P.,
PHYSICIAN TO THE MIDDLESEX HOSPITAL.

THE following case, as it is recorded in my note-book, possesses features of multifarious interest; it is here immensely abridged, and only those points are enlarged upon which stand in immediate relation to the liver.

W. H——, aged forty, a hawker and a hard drinker, was admitted originally on the 17th February, 1874. He had always been a strong man, and for the most part able to do the work of a professional pedestrian—walking at the rate of six miles an hour for two hours together—until four years before the date of admission. He then suffered from pain in the left side of the abdomen, much increased by the ingestion of food. In the course of half a year he entered the Brompton Hospital, and remained under treatment there for nine months, with enlargement of the liver accompanied by severe pain. At the close of that period his liver, so he was told, had become smaller. He himself assigned six weeks as the duration of his present illness, and latterly, it is true, he had vomited from time to time; but his abdomen had always been large, and his pains had continued on and off in a slight degree without increasing severity at any time during the whole interval of three years and a half preceding admission. His disease, then, must have been of long standing, and his own reckoning must be set aside altogether.

On admission he presented the physical signs of ascites, along with a trace of jaundice in the complexion. Dulness over the liver region enormously extended in every direction, below over half the abdomen as far as the level of the umbilicus, and above as far as the second rib, but here the extension is obviously owing to an abundant effusion into the pleural cavity, occupying the lower two-thirds or four-fifths of the chest on the right side. The dulness, however, fails to represent the full measurement of the organ, whose inferior margin may be traced an inch further downwards by palpation than by percussion. Everywhere over the abdominal area of the liver-dulness a sense of displacement is experienced when the fingers are pressed sharply home on the subjacent mass, and everywhere the surface of the organ underneath appears to be broken into ridges and hollows. In the region of the spleen there is dulness reaching as far as the transverse umbilical line, and, on long inspiration, even below that level. The hand may be easily inserted into a narrow gap between the opposing margins of the liver and spleen. Heart's impulse undulating and widely diffused, yielding a very extensive thrill. First sound loud and clear, especially at the left apex, where it is slowly evolved, hesitates, and, as it were, hangs fire. Ordered a powder consisting of tartarated iron and cream of tartar every six hours, and a draught containing copaiva three times daily.

Feb. 19th.—Girth of abdomen rapidly diminishing; fluctuation subsiding; urine double the normal quantity.

24th.—Jaundice disappearing. Patient wandered slightly during the night, and in the morning vomited a porringerful of greyish black muco-puriform matter.

28th.—To the left of the umbilicus there is a delicate purring sensation or fremitus plainly felt when the palm of the hand is laid lightly on the surface, but at once destroyed when the pressure is increased. At the same spot a humming sound may be heard on auscultation if the experiment be gently made, but the sound is at once abolished when the ear is applied firmly to the surface.

March 9th.—The fauces, and in particular the mucous membranes of the hard and soft palate, are intensely injected, and in many places pitted with hæmorrhagic erosions. Derived apparently from this source, large quantities of glairy-looking blood-stained sputa are expelled daily.

23rd.—The level of the percussion-dulness over the right back of the chest is now lower by three inches than on the date of admission, and all trace of fluid in the abdomen has disappeared. This day the patient received his discharge.

On the 18th of June, 1874, he was readmitted with signs of augmented effusion into the right pleural cavity. Thoracocentesis was proposed to him, but he resolutely refused to undergo the operation. He was again discharged on the 2nd of July.

On the 29th of December in the same year he was again readmitted in the following state:—There is dulness over the lower half of the chest on the right back, but free resonance from clavicle to nipple. No thrill can be felt at the heart's apex now, but the first sound is long, lagging, and briefly prefaced. The sputa continue to present the characters before described, and the membranes of the soft and hard palate are as vividly injected as ever. There are no physical signs of ascites. The left lower ribs beneath the mamma are much enlarged and rougher than natural, and in the same situation there is a prominent fluctuating mass, unaltered by position or pressure. The old purring and humming sensations may be elicited, as before, on the left of the umbilicus, but the seat of their production is no longer limited to that spot; they may be recognised just as clearly in the right hypochondrium under the same conditions.

On the 2nd of January, 1875, two ounces of laudable pus were withdrawn by aspiration from the abscess over the ribs. On the 26th occurred a sharp attack of fever, followed by commencing erysipelas on the face. At the same time a greyish-black, sloughing, superficial ulcer was seen to occupy a large portion of the velum and fauces. On the 31st hæmatemesis supervened on three several occasions, the blood lost amounting on the whole to about five or six pints. From this time forth to the close of life nothing of any moment ensued, with the exception of an attack of jaundice. The erysipelas, the hæmatemesis, and the ulceration of the fauces all disappeared entirely, and the man simply sank and died on the 15th of February.

Autopsy, condensed from Dr. COUPLAND'S *Report.*—Glands of groin enlarged; no scar on penis. Seated mainly beneath the periosteum of the tenth rib on the left side were the remains of an abscess occupying the two adjacent interspaces, and containing inspissated cheesy material, in which was found imbedded a fragment of the rib lying bare and detached from the rest of the bone. The left superficial epigastric vein was seen within the sheath of the rectus muscle to be greatly dilated; it was about the size of the little finger, and was traced towards the left and above the umbilicus, where it became very varicose; its further course was not followed, but a vein was observed on the ligamentum teres nearly the size of a crow-quill. The internal mammary veins were also enlarged and full of blood.—Thorax: On the right side the pleural sac was filled brimful with a clear dark-yellow fluid, showing a sediment of paler colour and creamy puriform appearance at the back near the spinal column. The lung, collapsed and carnified throughout, was dragged away from the spine by bands of adhesion attached to the extremities, but allowing the organ to hang free at the sides in the mid-cavity of the pleura. The left lung was unadherent, non-crepitant, intensely engorged, and dripping with blood. The inferior margin of the lower lobe was compressed by the adjoining spleen and collapsed in its whole extent. The mitral valve was competent to a stream of water projected through the aortic orifice, but the cusps and the chordæ tendineæ were greatly thickened.—Abdomen: The peritoneal cavity contained barely a pint of bile-stained fluid. The liver was displaced downwards; bands of adhesion passed from its surface to the parietal peritoneum; they were most plentifully supplied with bloodvessels, which were fully injected, and all running from the liver to the walls of the abdomen. The liver itself was strangely misshapen, its lobes being broken up by deep furrows into a multitude of irregular knobs, while the whole surface was more or less granular. The capsule presented numerous thickenings unevenly distributed. There was also well-marked fibrous thickening at the bottom of the furrows and along the course of the larger portal canals, and here and there were seen small tracts of caseous character in the midst of the denser material. The liver substance was throughout permeated and toughened by this fibrous change, so that it was nearly impossible to distinguish any individual lobules, the general appearance being that of fine granules, of various sizes and shades of colour, interspersed with larger masses of a dark-green tint. The weight of the organ was 56½ oz. There was no dilatation of the interstitial bile-ducts; in fact, their presence could hardly be ascertained. The hepatic and common bile-ducts were also free. The spleen was immensely enlarged. It was adherent to the parietal peritoneum; the capsule was dense, opaque, and puckered; the parenchyma firm, fibrous, dark-red, and liver-like. The mesenteric veins were fully engorged. The stomach was the seat of partial hour-glass contraction. The lining membrane was thick and firm, and everywhere of a deep slate-black colour. In the region of the fundus were numerous punctiform erosions, all surrounded by a zone of pigmentation, and some of their number filled with a black-coloured plug of altered blood. The entire mucous membrane of the intestines was exceedingly vascular and thick, while in the ileum the patches of Peyer were brought plainly into view on the red ground by their uniform slaty discoloration. The kidneys were enlarged, congested, and indurated. The testes were nearly normal. None of the viscera showed any trace of lardaceous degeneration.—Head: There was a clot found in the longitudinal sinus, and the vessels of the pia mater were full of blood. The dura mater and the brain-substance were healthy.

On a review of the foregoing case, it is impossible not to recognise that the root of all the mischief lay in the inflammatory attack that occurred four years and a half ago. Inflammation, however, does not exclude syphilis; and, if we are to accept the pathology of the present day, to syphilis we must refer the strange disfigurement of the liver described in the notes, in spite of many and grave misgivings, on the score of the following antagonistic facts:—The man himself stoutly repudiated the charge of syphilis, although he freely confessed to gonorrhœa; there were no manifestations of the disease in question on the surface of the body; there were no unequivocal gum-like formations anywhere; above all there was no evidence of amyloid degeneration. On the other hand, the round-topped eminences, flanked on each side by a deep cleft, at the bottom of which runs a stream of fibrous tissue, for the most part along the channels of the larger portal passages,—these are the very features which are held to be pre-eminently distinctive of the syphilitic liver in its outward configuration. They are, indeed, rough representations on the massive scale of what appears in the finer form and in miniature when the liver is simply cirrhosed. Not that cirrhosis is incompatible with syphilis; far from it, they are often associated. In our own case there was cirrhosis characteristically displayed in its truest colours.

Again, the caries of the rib and the abscess developed originally between the bone and the periosteum strike the balance in favour of syphilis, and far outweigh all presumptions to the contrary on the ground of the absence of gum-like formations or amyloid change. After all, the former may have had a real existence within the fibrous septa, and then disappeared, the caseous material remaining as the débris of their disintegration. In reference to the latter, it is, indeed, passing strange that syphilis should fracture a rib, and, while leaving its mark so strongly impressed upon the liver, should yet leave no trace of amyloid degeneration anywhere.

Clinically regarded, the following are the prominent points in the history of the case. Under the influence of copaiva the ascites passed away, at least so far as to be no longer discoverable during life. Other remedies were administered at the same time, but to copaiva I am convinced must be awarded the priority of place in the accomplishment of the cure. I have met with more than one marvellous illustration of the power of this medicine in dispersing ascites and restoring life where death appeared to be staring the sufferer in the face. It is, indeed, inconceivable that copaiva can in any degree modify the primary condition of the ascites—the disease in the liver itself. It is only a diuretic, but in many cases it is one of the surest and steadiest of its class, free and uniform in operation, allowing fair play to the overtasked veins, and giving them full leisure to recover tone and power to bear the strain of the exaggerated blood-pressure. In this way, by a course of strong diuretics, aided in the first instance by paracentesis, by hydragogues, and vapour baths from time to time, and by tonics throughout, we may indulge the hope of achieving a speedy cure of ascites in a minority of cases. In the majority the great point is to sustain the strength; the method of evacuation, though still indispensable, is now of less moment, and in the main we trust to the great physician Time, who works in a wholly different way, by the construction of new vessels or by the expansion of anastomoses already in existence, thus establishing what is known as the collateral circulation. In this point of view our own case becomes intensely interesting. I am not here called upon to enumerate all the by-paths in the circulation that conduct the portal blood to the right side of the heart when it is denied a free passage by its own high road through the liver. These are all well given by Dr. Goodeve in the article on Cirrhosis in "Reynolds's System of Medicine," and they were all beautifully illustrated by the disclosures of the deadhouse above recorded. I would, however, lay particular stress on the series of new vessels that pervaded the false membrane, on the enlarged superficial epigastric vein within the sheath of the rectus muscle, and on the enlarged vein coursing along the ligamentum teres; whether with Rokitansky we look upon the last-named vessel as the unobliterated and engorged umbilical vein, or with Sappey we regard it as one of the accessory portal veins. Be that as it may, it is a matter of the deepest moment, in cases of cirrhosis, to ascertain, if possible, during life, whether the collateral circulation be fairly well established or not. What evidence, then, have we bearing on this point? Of course in a large proportion of cases we see the uppermost vessels conspicuously streaking the surface of the abdomen. Below the surface there runs an unseen auxiliary circulation, whether conveyed by channels nominally superficial or nominally deep-seated. Have we any evidence of this drainage that is going on underground and out of sight? With regard to the deeper strata of bloodvessels, I cannot say with absolute certainty that we have, but with reference to those which, though invisible, are yet immediately underneath the surface, our own case is conclusive as far as itself is concerned. We had the clearest evidence on this score in the purring sensation and in the humming sound perceived exactly over the spot corresponding to the enlarged superficial epigastric vein, and again towards the right hypochondrium over the seat of the vascular false membrane, and not far from the neighbourhood of the ligamentum teres. I dare not, however, presume to apportion precisely to the respective vessels their several shares in the production of the aforesaid phenomena, beyond simply saying that the superficial epigastric vein must have been one of the sources of origin, if not the exclusive one. Let that pass. The sign, if it can be verified by repetition hereafter, will possess some value with a view to forecasting the future of a case. I need not say that it will be a sign of good omen, for it signifies a free collateral circulation. This freedom of the circulation it will be our duty to develop and maintain—principally by tonics, in order to strengthen the reconstructive energies of the system; in a minor degree by the method of evacuation, in order to lessen the amount of fluid within the abdomen, and to relieve tension, which, over and above other evil agencies, would choke the bloodvessels and preclude their development. Well, we cured the ascites, and in all likelihood the collateral circulation prevented its recurrence in any degree appreciable during life. It did not, however, prevent the recurrence of that hæmorrhage into the stomach which was the main element in the multitude of causes that led to the man's death, and perhaps for this reason. In cirrhosis of the liver it is quite true that hæmorrhage into the alimentary canal is in great measure determined by mechanical congestion; but there are secondary processes at work. The blood or the bloodvessels, or both together, must have undergone degradation; for hæmorrhages occur in other regions far away from the portal system, not only in cirrhosis but in a variety of liver diseases. This point also has been well laid down by Dr. Goodeve, and it is amply illustrated in our case by the blood-stained sputa and the prolonged engorgement of the mucous membranes of the palate and fauces. In truth, the hæmorrhagic erosions of those membranes so conspicuous during life were the very counterpart of the appearances revealed after death in the membrane of the stomach. We thus arrive at the melancholy truth that in removing ascites even for a permanency, we do not remove all the dangers of cirrhosis: the danger from hæmorrhage still remains.

I have not dwelt upon the use of iodide of potassium. Of course, in cases like the foregoing, it must be tried by way of a preventive measure in order to stop the ulterior progress of advancing syphilis. Beyond this it will be of no avail. When once the characteristic changes in the liver are well pronounced, when once ascites and hæmorrhage have supervened, iodide of potassium will no more undo the mischief that has been done already than it will abolish a cicatrix. I gave it a fair trial, and found it utterly useless.

RELIGIOUS INSANITY AND RELIGIOUS REVIVALS.

EFFECTS OF THE "MOODY AND SANKEY SERVICES."

By GEORGE H. SAVAGE, M.D.,
ASSISTANT MEDICAL OFFICER, BETHLEM HOSPITAL.

We see the periodical return of mercantile and political storms, and likewise we see the religious atmosphere agitated if not cleared by recurring revivals. These agitations are of interest to all, but especially to the student of insanity; for in them we have a widespread cause acting on a large number of persons of different temperaments. It behoves us to see how far the recent religious revivals have caused or precipitated insanity. In the following remarks I must be understood merely to contribute my limited experience in the hope that others will add other facts that may enable us to weigh the effects of the disturbance. I purpose examining the cases of insanity associated with religious delusions as symptoms, and those distinctly associated by a history of attendance on the services as a cause. Probably in many cases religious excitement, if it produce insanity, produces it of a type that may be considered religious; but though a general truth, this is not a necessary one. We shall examine the cases that have been admitted into Bethlem Hospital during the past four months—from April to August,—and compare these with the admissions during the same months in 1874 and 1873. We shall more particularly compare the cases that may be called those of religious insanity.

I do not look upon religious insanity as a special well-defined class. It seems to me to be almost an accident of education, temperament, or sex, whether certain subjective feelings develop themselves into a morbid religious idea, or one of some form of persecution or annoyance by others. It is false sometimes to attribute an outburst of insanity to attendance on some exciting kind of religious service. Many persons verging on insanity—in fact, in the melancholy stage of the disease—seek religious consolation, and notwithstanding this go mad; they would probably have gone mad in any case, and the most that can be said against the service is that it precipitated the attack.

In confirmation of my statement that there is no such disease as religious insanity apart and separate, I may say that among our cases we have some of general paralysis with religious delusions. One patient, who sank rapidly, was a Wesleyan, who was going to reform the world and build churches and chapels and save all sinners; another general paralytic had his ideas for ever running on the fate of Sodom and Gomorrah. On the other hand, we had cases of the most acute mania, in which religious delusions were the chief ones. Thus, one man, aged fifty-one, who had had previous attacks, was admitted in a state of great excitement. He came, he said, as "God the Father," for he found that though he had come to earth as "God the Son," that was of no good; man sinned as much as ever; so now he had come to empty hospitals and asylums in his real character.

Melancholia in some form or other was, however, the more common condition of our patients labouring under religious delusions. Some fancied they were possessed by the Devil, others that they had lost their souls or had committed the unpardonable sin.

We were quite unable to find any cause that was common. In some cases age seemed the predisposing cause, and in others exhaustion, that form of exhaustion due to masturbation being rather common in both sexes.

I have taken as cases of religious insanity those whose delusions or hallucinations referred to subjects which are considered as questions of religion. Thus a woman who considered herself the Bride of Christ would fall into the same class as the woman who thought herself the "Red Whore of Babylon."

Most of the cases of religious insanity were of slow growth; some associated with gradual physical enfeeblement; and there were odd associations in the symptoms, one person not only believing that he had lost his soul, but also the passage through his bowels. I cannot say that I see grounds for supposing many cases were rendered insane by the recent revivals. Many persons were no doubt upset for a few hours, rendered very wretched, and for a time determined to lead a different life. The good done is not for me to discuss; it may have been small or great, temporary or permanent; in the majority of cases the storm was of short duration and did little harm. No doubt we shall have objectors. Some will say the time has not yet come to weigh the effects of the revival; yet I would reply that this may be true, but let us be ready to collect and observe from the first. Again, a general cause may result in an increase of all sorts of insanity, and therefore one would be judging more safely by taking all cases of mental disturbance into consideration. I have tried to do this as well as I could.

We now proceed to examine the lists of cases admitted during the four months named of 1875, '74, '73. We take 1875 first as the year we are most interested in.

In 1875, from April till August, 42 male patients were admitted; of these 9 suffered from religious insanity. During the same time 55 women were admitted, and of these 8 had religious delusions. That was 21·4 per cent. of the men, and 14·5 per cent. of the women.

During 1874, in the same period, 30 male admissions gave 6 religious cases, and 47 female cases gave 16 religious; that was 16·6 and 34 per cent. respectively.

In 1873, 28 male admissions gave 4 religious cases, or 14·2 per cent.; and 28 female admissions gave 8 religious, or 28·4 per cent.

The only striking thing in these numbers is the increased number of admissions during 1875, and this is only in part brought out, for on the female side we became completely full, so that many were refused. On the male side we have had more admissions than for very many years.

Religious revivals, as I said just now, do not always, after unhinging the mind, leave a religious débris. A strong feeling may stop or interfere with sleep, so that the person dreams in his disturbed sleep, and yet the perturbing idea is often absent from the dream.

I can find nothing noteworthy either in the ages or social conditions of the patients admitted; the ages were the same in general in 1875 as in the other years.

Cases are more common in my experience in young middle-age than earlier. Cases are seen under twenty, but usually the shock is slight, and passes more rapidly than after thirty-five. Singleness, both in men and women, predisposes to religious insanity; no doubt masturbation is one of the causes of trouble, the intense feeling of degradation, associated with physical exhaustion, causing the patients to think they are utterly undone. I believe most of the patients who think they have sinned against the Holy Ghost have sinned in this way.

During 1875 we had more admissions from among members of the Church of England than from Dissenters; this was true of both the male and female admissions. Generally, in cases with marked religious delusions, we found among the women an excess of Dissenters. A woman's religion, especially if a Dissenter, is a very great power. Among the men the majority have been born Churchmen, and remain such, though rather indifferent.

During the three years the religious persuasion of the patients under consideration was as follows. Among the men, there were 9 members of the Church of England, 3 Dissenters, 1 Roman Catholic, 4 vaguely Protestants, and 2 unknown. Among the women, 14 were of the Church of England, 11 Dissenters, 6 Protestants, 1 unknown.

The hereditary predisposition was rather well marked in our cases during 1875, but in the other years we had only the ordinary percentage of hereditary taint.

And now, to particularise, we have several cases in which the "Moody and Sankey services" were given as the one cause of the insanity.

Case 1.—H. W——, a male, single, a clerk, aged twenty, Congregationalist; no hereditary taint. He heard several of the revival services. No marked change at the time, but he began to be moody and desponding, and to be careless in his dress and inaccurate in his work. The earliest symptoms were about May 1st. On admission he was pale and anæmic, suspicious, and melancholy. He has made but slight progress, and still keeps to himself. Requires feeding and dressing. He is said to have been a masturbator.

Case 2.—Thomas K——, single, aged twenty-seven, a draper's assistant. There is a history of insanity on the maternal side, but this is distant. He belongs to the Church of England. His earliest symptoms followed hearing Moody and Sankey early in May. He had hallucinations of hearing, and was easily induced to believe anything that was said; thus he acquiesced in being Christ. He said the Devil prompted him to do evil; that he fought the Devil and kicked him three inches. He, too, hears God's voice, which tells him to abstain from food. He has remained in much the same state, and has to be fed forcibly twice daily.

Refusal to take food is a common symptom with these patients, and we have had examples of the many delusions that may each induce the refusal to take food: one because God claims the patient as his Son, and tells him not to eat in an asylum; another because of the text about not "living on bread alone"; others because they are either too wicked to live or have compacted with God or the Devil never to eat again.

Case 3 was that of a woman, Mary A. H——, single, aged thirty-five, a dressmaker, Congregationalist, admitted in April. She had had a disappointment in love. She had heard Moody and Sankey, but did not seem to have been affected much. She gradually developed various delusions. Said she had lived in America. She also considered herself an evangelist, and called herself "Moody and Sankey." She would sing or preach on request, though her voice was unmusical and her oratory nonsense. She was noisy, boisterous, and untidy. A few days' residence in Bethlem produced a great change, and she rapidly got well, and was discharged three months after her admission.

These are the only cases that are distinctly traced to this revival among our patients. We have to admit a serious increase during the past four months of general cases, and these may represent in some part the results of the moral commotion.

A person of weak mind may change his creed, and finally become a religious lunatic. We have at present two cases of men who have changed from Protestantism to Roman Catholicism just on the eve of an outbreak of insanity. The history of one is interesting, as it is that of many similar cases. A. T——, the son of a Church of England clergyman, single, aged twenty-five, whose mother is insane. He was precocious, and had the vices of a man before he was seventeen. He wasted his own money and that of his friends, and was a "black sheep." He becomes contrite, or I would say melancholy, becomes a Romanist, and wants to be a priest. He is emaciated with fasting and self-abuse, and restless, constantly repeating some such word as "immaculate." He may be considered in an ecstasy by some. We look on him as an acute maniac.

So, in conclusion, I would say that my experience is that religious revivals do but small harm to the able-minded, but to those who are weak there is danger. But there will always be sufficient sources of religious excitement without revivals to provide a flame for the fluttering moth.

Bethlem Hospital.

Patent Medicine.—In the year ending the 31st of March last the stamp duty on patent medicines, as appears from a Parliamentary document just issued, amounted to £114,322 15*s.* 7½*d.*

CASE OF

PERINEAL SECTION, FOLLOWED BY THE OPERATION OF DR. OTIS, FOR THE CURE OF FISTULA IN THE PERINEUM.

By WALTER COULSON, F.R.C.S.,
SURGEON TO THE LOCK AND ST. PETER'S HOSPITALS.

The following case, considerably abridged, may serve as an introduction to some remarks on perineal fistula, and on the operation for stricture proposed by Dr. Otis of New York, and recently performed in this country.

The case is that of Robert D——, aged forty-four, seaman. About five years previous to his admission for the second time into hospital he had been treated for stricture, as an in-patient, by dilatation, at Guy's Hospital.

Two years ago (1873) he was admitted with extravasation of urine following retention. This condition was relieved by free incision of the perineum. The patient made a good recovery, but a perineal fistula remained, which it was hoped might be closed by continuing dilatation of the stricture. At the time of his leaving the hospital a No. 5 silver catheter (English scale) could be passed into the bladder; but the man neglected to attend as an out-patient, and when readmitted, in May, 1875, he was unable to pass any urine naturally, the whole of it escaping in a small stream through the perineal fistula. The passage of the urine now causes great pain and scalding, which continue for some time after micturition; he suffers from a constant desire to micturate, the urethra is excessively sensitive, the urine loaded with mucus and pus, and no instrument can be passed into the bladder. Up to the 17th of May several attempts had been made to pass elastic instruments into the bladder by the penis and through the perineal opening, but they failed. He has been taking fifteen minims of sandalwood oil three times daily, which has materially diminished the muco-purulent deposit in the urine, but has had no effect in diminishing the scalding. On two occasions he had retention of urine, which was relieved, after some difficulty, by insinuating a small elastic instrument through the fistulous opening into the bladder, but all attempts to pass an instrument along the penis from the meatus were unavailing. However, an extremely fine elastic bougie could be passed along the penis and out at the perineal opening.

On May 17th I performed the following operation:—A No. 8 steel bougie was passed down along the urethra, as near to the fistula as the thickened structures surrounding it would permit. A free incision was then made through the fistulous opening, and the adjacent strictured portion of the urethra was freely divided. A straight-grooved director was then passed through the wound into the bladder, the edges of the fistula were pared, and a No. 16 French elastic catheter was introduced into the bladder, the straight director acting as a guide. The catheter was tied into the bladder, and there retained until the following evening. No bad symptoms followed the operation, and the temperature of the patient remained unchanged. From this date until July 19th, both continuous and occasional dilatation was employed, and the edges of the wound were from time to time touched with caustic. The perineal wound became merely a fissured opening, but still it would not quite heal, and on every occasion that the patient passed water, some portion of the urine escaped through the fistula. The question then presented itself whether the fistula might not possibly be kept patent by some constriction in the penile portion of the urethra. With the assistance of Dr. Otis an examination was made with the urethrometer, and the existence of three distinct points of constriction was demonstrated. It was therefore resolved that resort should be had to his operation. The patient was placed under the influence of ether administered by Mr. Knott, and the urethrotome of Dr. Otis was passed down as far as the fistula. The instrument was then made to indicate a dilatation corresponding to 32, French scale, and the three points of contraction were freely divided. The last-mentioned result was verified by the introduction of the bulbous sound (Fig. 1), which was passed down as far as the fistulous opening, and withdrawn without a catch. A cylinder (Fig. 2), open at both ends, and about five inches long, was tied into the urethra after the operation, and was allowed to remain in for six hours. This was done at the suggestion of Dr. Otis, but the cylinder was removed at the patient's request, as there was no sign of bleeding; the loss of blood after the operation was also slight. From the date of the operation, July 19th, to the 24th, no unfavourable symptom manifested itself. A No. 32 bougie was daily passed along the urethra to prevent adhesion, and the patient left the hospital cured. When he reported himself to me, Aug. 16th, the fistula was completely healed.

FIG. 1.

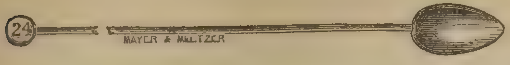

FIG. 2.

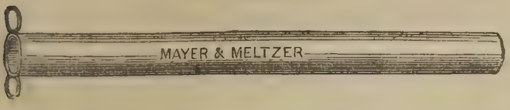

Before making any observations on this case, it may be well to notice the principal features of Dr. Otis's new operation.

The method of Dr. Otis is based on the simple proposition "that in all contractions of the urethra the contractile points must be reduced to the normal calibre of the urethra in its healthy state." This applies to all deviations, and, in Dr. Otis's view, especially to "comparatively slight contractions," which are not usually considered as requiring operative treatment. The term "slight contractions" refers to strictures which only admit 8 or 9 of the English scale. Dr. Otis maintains, as I have said, that any deviation from the normal standard, however slight, should become the subject of operative interference. The urethra must be brought back to its "normal calibre." But what is this normal calibre? According to Dr. Otis, "the capacity of the urethra always bears a constant relation to the size of the individual penis, which latter varies greatly in different individuals."*

Thus, in the past year alone, Dr. Otis examined more than one hundred urethræ carefully. His conclusions are that the flaccid penis varies from three to four and a half inches in circumference, according to the individual, and that the circumference (or capacity) of the urethral canal varies from 30 to 40 of the French scale. Also, if we reduce the tables, every increase of one quarter of an inch in the circumference of the flaccid penis implies two degrees increase (as French scale) for the capacity of its urethral canal. Besides this, the urethrometer devised by Dr. Otis (Fig. 3) furnishes, according to him, in all cases, the exact normal calibre of the urethra; and to this calibre the diseased urethra must be brought in order to ensure a cure.

From what precedes, it follows that the surgeon must begin by ascertaining the normal calibre of the individual urethra. This ascertained, we have various methods of "sundering" the stricture at some point. The selection must rest on the judgment of the operator; but whatever method may be selected—whether rupture, dilatation, or division—*every* fibre of the constricting tissue must be completely severed, or subsequent recontraction is cèrtain.

FIG. 3.

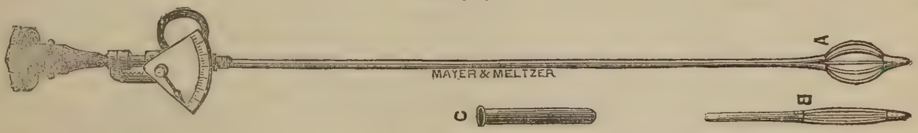

FIG. 4.

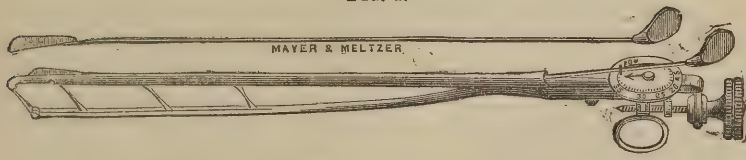

To ensure the attainment of these objects, Dr. Otis has devised a new form of urethrotome, which combines dilatation with division, though the object of dilatation is chiefly to enable us to apply the edge of the blade more surely to the structures which we intend to divide, and thus to protect, or nearly so, the healthy portions of the canal (Fig. 4). All the bands which obstruct the canal must be divided one after another, if not detected at first. Dr. Otis never practises dilatation after the healing of the wound made during the operation. The incision, it may be observed, is along the superior wall of the canal, against which the dilating portion of the instrument forcibly presses the blade. The use of the sound after the operation is simply to separate the divided surfaces, not to dilate. The after-treatment consists merely in separating the wound throughout its extent by the easy passage of a full-sized steel sound daily, or every other day, until healing is complete. Finally, as recontraction of stricture after operation is simply due to incomplete division, and as the latter, as a rule, will be detected within one or two weeks, the cure may be considered complete after the expiration of that time if no change of calibre be detected. For a second operation, however, Dr. Otis frequently employs one of his earlier urethrotomes, which cut only at a single predetermined point, and the blades of which are not protected by a guard. He also maintains that in all long-standing cases of gleet contraction exists in some point of the urethral canal, and that such cases are cured by his operation. I am collecting twelve such cases myself, of not less than two years' duration, in which the operation has been performed. The results of these I hope to make known at some future time. Meanwhile a few observations may not be out of place here.

The operation just described, and the instruments employed, seem to present advantages over any other operative methods with which I am acquainted for the internal division of strictures in the penile portion of the urethra, and, so far as the mere division of the strictured part is concerned, it fairly fulfils all which the author claims for it. Another advantage which Dr. Otis attributes to his method of operating is that recontraction does not take place after cicatrisation of the divided tissues. If this be fully confirmed by subsequent experience, we must admit that the new operation effects what no other operative proceeding has effected—viz., a radical cure of stricture; that is to say, a condition of the urethra which shall require no future introduction of instruments.

Amongst the complications arising from stricture, extravasation of urine, and injury to the urethra, there are few which occasion more inconvenience to the patient and trouble to the surgeon than perineal fistula. In D——'s case the complication resulted from an operation performed for the relief of extravasation, and, dilatation having been tried and failing to close the fistula, perineal section was for a second time resorted to; but, in spite of this operation and subsequent dilatation, the fistula remained open.

The result of Dr. Otis's operation certainly proved that slight contractions which are not usually recognised as strictures may offer obstruction to the passage of the urine sufficient to prevent a urinary fistula from healing. The result of the internal division of the strictures and the daily introduction of full-sized instruments left the mucous wall of the canal, after complete cicatrisation had taken place, as supple and non-resisting to the passage of the full-sized sound as a perfectly healthy urethra. Dr. Otis finds that this condition has continued for three years after the operation, and believes this result to be due—(1st) to complete division of every fibre of the stricture, and (2nd) to the prevention of contraction of the internal wound during the process of cicatrisation.

---

* It appears to me that this proposition involves the assumption that, in the healthy state, the calibres of the penis and of the urethra remain respectively unvaried from the meatus to the prostate.

The ultimate success of the operation must depend on the permanency of this result, and at present it is impossible to express any positive opinion on this point until we have ascertained by pathological investigation what the precise nature of the cicatricial connective tissue may be. Up to the present time I have performed this operation for stricture in the penile portion only. But change of position may require a change of practice. In the sub-pubic portion of the urethra we often meet with old strictures which are dense in structure and resist dilatation. Forcible dilatation and incision employed in such cases might readily give rise to local or general accidents of a very severe nature; and hence subcutaneous division of the contracted tissues should probably be preferred as less liable to be followed by the evil consequences just mentioned.

St. James's-place, S.W.

BRAINS AND INTELLECT.

By ROBERT LAWSON, M.B.,

PATHOLOGIST TO THE WEST RIDING LUNATIC ASYLUM.

IT is surprising, after the amount of labour that has been spent upon the subject, how little definite information has been acquired about the relation between weight of brain and extent of intellectual capacity. It is true that Cuvier, Abercrombie, Dupuytren, Goodsir, Simpson, and others whose brain-weights were accurately ascertained, were found to have cerebral centres of considerably more than the average weight; but even these did not attain to the known maximum. The 64 oz. brain of Cuvier is in some respects balanced by the 65 oz. brain observed by Tiedemann and the 61 to 62·75 oz. brains commented on by Dr. Peacock, the living representatives of which seem to have possessed no corresponding superiority over their smaller-brained contemporaries. Perhaps, indeed, if all the elements of the case were to be considered, the heaviest adult brain on record might be found to be that of a senile dement who died in the West Riding Asylum at the age of seventy. His brain was found to weigh 61 oz. Following the generally accepted principle that the brain loses weight to the extent of an ounce in each decennial period, this man's brain, after allowance has been made for physiological diminution, may be presumed to have weighed, when he was at the age of forty, no less than 64 oz. But in his case pathological supplemented physiological changes, and the more rapid atrophy which accompanies senile dementia justifies the conclusion that at the time of his maturity this man's brain may have outweighed that of the great Cuvier.

Investigations prosecuted at the West Riding Asylum by Mr. W. C. S. Clapham, and commented upon by Professor Turner,[*] show how fallacious any general principle would be which tended to establish a direct and exclusive relation between mere weight of brain on the one hand and capacity of intellect on the other. By a compilation of the brain-weights of 705 patients who died in this asylum, Mr. Clapham showed that the average weight of brains in the insane was little if anything below the commonly accepted average of 49 oz. in sane males and 44 oz. in adult females. And if the average brain of the resident lunatic and the obscure dispensary and hospital patient can reach a satisfactory average weight, the heavy brains of the same classes of the community also contrast well with the brains of sages and the members of sane society of the general type. There is the 61 oz. brain of the aged dement who died in this asylum; the 60 oz. brain of a boy of fifteen, as cited by Professor Turner; the brains referred to by Dr. Peacock and mentioned above, ranging in weight from 61 to 62·75 oz.; and the numerous instances in the records of the West Riding and other lunatic asylums in which male brains are noted as weighing from 58 to 61 oz., and female brains from 50 to 56 oz. When the brain-weights of men who have earned fame in science, philosophy, or politics are directly compared or contrasted with those of men whose lives have been mute and inglorious, and even despicable, they are by no means so striking as when quoted by themselves. Thus—

Brain-weight of	Dr. Chalmers,	53 oz.	...	Lunatic,	58 oz.
,,	Daniel Webster,	53 5	...	,,	58
,,	Sir J. Y. Simpson,	54	...	,,	58·5
,,	Goodsir,	57·5	...	,,	59·5
,,	Abercrombie,	63	...	,,	60·5
,,	Cuvier,	64	...	,,	61

The weights of brain in Abercrombie and Cuvier cannot be directly balanced by any West Riding Asylum brains, but could be fairly contrasted with the 63 and 65 oz. brains observed respectively by Reid and Tiedemann. The brains also of female lunatic patients, when placed in the balance, are not necessarily found wanting. Mr. Clapham's figures show that amongst rather more than 300 insane women, brains were found weighing from 50 to 56 oz., and which, in acknowledged proportion, were equal to male brains of 55, 58, 60, and 61 oz. Relatively speaking, these insane women had more brains than Chalmers, Webster, Simpson, Goodsir, Lord Campbell, and many others adduced as illustrations of the statement that great size of brain usually accompanies great intellectual capacity. Similarly with regard to criminal lunatics: though the average weight of brain amongst a single dozen of these, examined by Dr. Orange of Broadmoor,[*] is an ounce and a half under the general male average, there are in that limited number two brains which exceed that of Chalmers in weight, and one which outweighs those of Chalmers, Daniel Webster, and Simpson, and is within half an ounce of being equal to that of John Goodsir.

But if the occasional occurrence of very heavy brains amongst men of great ability is no proof of the general proposition that all men of great intellectual capacity have heavy brains, neither is the fact that very heavy brains are found amongst lunatics proof that large brains are not, *cæteris paribus*, characteristic of the capability or existence of great mental power. The occurrence amongst men of great ability, or even genius, of instances in which lunacy may be regarded as having tinged the products of their minds, and in some instances impregnated their works with the impassioned fervour which alone ennobles them, shows that such an assumption would be altogether gratuitous. Such men, for instance, as Byron, Shelley, Poe, Lamb, Cowper, and, in some degree, Dean Swift, have given evidence in their writings and their lives of such a taint. From the time of St. Paul the fervid apostle, Lucretius the philosophic and Dante the melancholic poet, down to that of Dr. Johnson, the apostle of common sense, the men are numerous who have had ascribed to them the combination of much learning and more or less madness; and even in more recent times a veil lies over the lives of many of our great men and great women, which, if it were to be removed, would show that some of those who have charmed us with their brilliancy and helped to mould us by their power have not been exempt from the occasional or constant workings of the genius of insanity. Every day the observation of the poet that great wit is nearly allied to madness gains a wider and more practical acceptance. So much is this the case that Dr. Wilks, in a very thoughtful and suggestive paper in a recent number of the *Journal of Mental Science*, ventures to make the statement that probably "it is the insane element which imparts what we call genius to the human race, the true celestial fire; and thus it is that the madman has been called inspired and thought to have in him a touch of the divinity."[†] Though it is fearful to think of the propagation of a race tainted with insanity, yet, says Dr. Wilks, "it does not follow that an infusion of the insane blood may not be desirable. I think it might easily be shown that such infusion has given genius to a whole family; it has leavened the whole mass." Dr. Maudsley holds the same opinion; and, however painful the observation may be, there can be little doubt that it is marvellously true.

---

[*] West Riding Asylum Medical Reports, vol. iii., 1873.

[*] Annual Report, Broadmoor Criminal Lunatic Asylum, 1873, p. 57.

[†] The Study of the Human Mind. By Samuel Wilks, M.D. (Journal of Mental Science, Jan. 1875.)

A pauper lunatic asylum is a very unfavourable field for judging of the relation between brain-weight and intellectual capacity. Imperfections of education in the patients with which one has to deal prevent the manifestation of intellectual capacity. The commonplace and the potentially superior mind meet on the common standpoint of mediocrity. The reiteration of uneventful and almost stereotyped histories frustrates the scientific observer in his endeavour to detect in the recorded lives of large-brained pauper lunatics any prior evidences of superior power in developing or utilising the circumstances of a healthy social existence. Still, it sometimes does happen that one can determine, by an inquiry into the history of the insane, that men with unusually large brain-weights were during the sane period of their existence characterised by greater mental vigour and higher intellectual capacity than their station in life would have led one to expect. Such a case occurred in this asylum shortly after the compilation of the statistics of Mr. Clapham and the observations of Professor Turner.

A. B——, a weaver aged forty-five, was admitted last year on account of a first attack of mania. In the form of admission it was stated that the patient had been talking incoherently upon religious subjects and the making of wills; that he was restless, and, when restrained, violent; and that he was indecent in his acts. He was not epileptic.

About six weeks before admission the patient became depressed. This depression lasted for about a month, and was succeeded by excitement. He became incoherent and at times obscene in his conversation, and violent to those about him. He attempted to bite those who were guarding him, and during the night left his bed and caused annoyance to his neighbours. Having become quite unmanageable, he was certified for removal.

Two cousins had been insane, and one of them had been treated in an asylum. It was satisfactorily determined that the patient had been an unusually sober and steady man, even though his symptoms on admission resembled in some particulars those characteristic of the prostration following upon excessive drinking.

A searching examination into his history led to the determination that he had been regarded by his fellow-townsmen as a very intelligent man. He was very fond of reading, and devoted special attention to the study of religious subjects. He had written a good deal, mainly on religious topics; and showed a remarkable memory, which was chiefly manifested by the repetition of large portions of any sermon which he had heard. He had an ambition to qualify himself as a preacher and engage in missionary work. He was also a recognised leader in politics, was regarded as the leading man in the agitation relating to the establishment of the School Board in the town where he resided, and during all political contests was relied upon as an influential agitator in the Liberal interest. He appears to have been much addicted to controversy, and the excitement of argument is said to have induced frequently a violent pain on the top of the head, which compelled him to abandon for a few minutes his share in the discussion. For eight or nine years he had suffered from headaches, which were much intensified by reading.

On admission he was very restless and excited. He talked incoherently, and was very anxious to make a long statement about some conveyance of property, payment of succession duty, and indemnification for losses. He refused food, and at night lost sleep under the influence of delusions; he also had hallucinations of smell, delusions of a prurient nature, and a further delusion that his head or body had been changed during the progress of some surgical operation which he had undergone. His tongue and all his muscular movements were tremulous. With the exception of incontinence of urine and disorder of the alimentary system, he had no bodily ailment. His temperament was sanguineous. When admitted, his weight was 168 lb., and his height 5 ft. 9 in. A fortnight afterwards he showed signs of inflammatory action affecting the right side of the chest, and in another week succumbed to an attack of double pleurisy with effusion.

On post-mortem examination, it was found that the body was well nourished, but the limbs were somewhat œdematous. The skull-cap was capacious, but normal in thickness and density, and symmetrical. During the removal of the brain little or no fluid escaped. Beyond the existence of a limited amount of subarachnoid extravasation of blood into the sulci, the brain appeared to present nothing abnormal; at the same time the sulci were narrow. The pia mater was thin, and on that account stripped with difficulty; but there were no adhesions. *The weight of the whole brain was 61 oz.* The convolutions were plump and well differentiated, especially in the second frontal tier, and showed no sign of having been compressed. The measurements of the head were: from root of nose to occipital protuberance, 15 in.; from meatus auditorius, left to right, 15½ in.; circumference round middle of forehead and over occipital protuberance, 23½ in.; diameter of cranial *cavity* from before backwards, 6⅞ in.; ditto across, 5⅜ in. A large quantity of serous fluid was found in each pleural cavity, and a patch of grey hepatisation occupied part of the lower lobe of the right lung posteriorly.

Observations.—The patient in this case was known by his associates to have been a man of superior intellect. His brain-weight after death proved to be greater than the external measurements of the head might have led one to anticipate. Amidst the evidences of more than ordinary mental capacity, he occasionally showed signs of the existence of some unhealthy intra-cranial condition. Occupations involving a congestive state of the cerebrum induced violent coronal pain, which was alleviated only by his desisting from the study or the discussion which had induced it. Ultimately he fell into a short depressed condition, which was followed by an attack of acute mania and the development of fatal physical lesions. On post-mortem examination his brain was found to be 12 oz. more than the average weight in adult males. That the large size of the brain was not due to effusion into the ventricles was shown by the very limited quantity of fluid which escaped on removal and section. That it was not due to any recent condition of hypertrophy was evident by the plump appearance of the convolutions and the absence of all signs of compression. On the other hand, the plumpness and the complexity of the gyri, and the previous definite history of the patient's proclivities and accomplishments, go to show that he had normally a heavy brain, which, in his limited sphere, he exercised in such a manner as to secure a character for intellectual superiority.

Similar cases are of not infrequent occurrence.

M. W——, aged thirty-six, was admitted into the Durham County Asylum* in July, 1873. His mind had been deranged for about four years previous to that date. On admission he was epileptic. He was incoherent in his talk, showed great loss of memory, and was very inconsistent in his statements, affirming that he had children of the age of thirty-five, though he himself was only thirty-six years old. He was restless at night, left his bed, roamed about the house, and was unable to return to where he started from. He had attacks of excitement. During his residence his condition was that of dementia. He had occasional epileptic fits and several attacks of syncope. Before and after the fits he was very stupid. On admission his physical condition was fairly good. He died in June, 1874, and the cause of death was fatty degeneration of the heart and bronchitis. *The weight of his brain was 60 oz.*

This patient had had little early training, and in his youth was a steady, hard worker, who devoted his leisure hours to the acquirement of elementary education. He was born in the very lowest ranks of society, and by perseverance and industry advanced himself to a condition of comfort. He commenced life as a labourer, but soon raised himself to the position of a rag and bone merchant, with a horse and cart of his own; and finally, by industry, economy, and ability, was able to start in business as a marine store dealer. He saved £600, and brought up his family comfortably. It appears that he retained his mental acuteness till he discovered almost simultaneously that his wife had become a drunkard and squandered all his hard-earned savings, and that his daughter had abandoned herself to public prostitution. These discoveries threw him into a state of excitement, and at that time he had his first epileptic fit. The fits recurred at rare intervals, and were isolated. They were preceded by stupor and giddiness.

---

* For the particulars of this and the following case I am indebted to the kindness of Dr. Smith, medical superintendent, and Dr. Wallis, late assistant medical officer, Durham County Asylum.

While at the Durham Asylum he was quiet and demented. He died after a few days' illness.

J. H—— was for the second time admitted into Durham County Asylum in July, 1862. He was suffering from recurrent mania. The patient was a member of a family characterised by good physical and mental development. He gradually sank into a condition of consecutive dementia, but continued to manifest considerable ability, especially in making calculations. He wrought out complex arithmetical problems mentally, and with great readiness and correctness. In early life he was an agricultural labourer, and pushed his way on so steadily and showed such special capabilities for the work that he secured the appointment of road surveyor of a district. He was regarded by all who knew him as a man of great original ability. He never reached any great amount of dementia, and within three months of his death gave clear evidence regarding an assault of which he had been a witness. He died on the 25th of June, 1870. *His brain weighed between* 60 *and* 61 *oz.* The condition was one of atrophy, associated with atheroma of the cerebral arteries.

It is worthy of renewed notice that, in the brain referred to in the first case recorded in this paper, the complexity of the convolutions is quite as characteristic as the unusual weight. As I have not seen the brains referred to in the last two instances, I am unable to say what was the extent of the differentiation of their gyri; but the general principle that multiplicity of gyri is more characteristic than large size as a gauge of intellectual capacity may readily be accepted as a safe one.

West-Riding Lunatic Asylum, Wakefield.

DEATH FROM THORACIC ANEURISM.

REPORTED BY

SURGEON HENRY C. WOODS, M.D., R.N.

(*Communicated by the* Director-General of the Medical Department of the Navy.)

The previous history of this most instructive case has been already fully reported, and further published in The Lancet of July 5th, 1873; a brief *résumé* is, therefore, only given.

J. F——, aged thirty-five, a private in the Royal Marine Light Infantry, with now fourteen years' service, was admitted on the 3rd of June, 1872, with a small left femoral aneurism immediately below Poupart's ligament. He was a spare, rather aged-looking man, with dark hair, sallow complexion, and slight arcus senilis. He had on the 20th of May first noticed pulsation in the groin, no cause being traceable. Intermitting digital pressure, and subsequently persistent for forty-eight hours, and acute flexion, failed to procure consolidation. On the 20th of August the anterior iliac was secured by Fleet-Surgeon John Elliott, R.N. (then in charge of the hospital), a carbolic-gut ligature being used, and the ends cut short off. The wound was dressed with carbolic solutions, &c. On the 23rd, a slight erysipelatous blush appearing, the dressings were removed. The wound appeared to be healing by the first intention. Free suppuration was, however, afterwards set up. On the 25th a faint pulsation was detected, and soon became confirmed; the sac then steadily and slowly enlarging. The gut had evidently absorbed and permitted the circulation to be re-established. Pressure with a Carte's tourniquet (which proved successful in a similar case at the same time under treatment), flexion, and distal pressure were again tried, and failed. On the 26th of November the artery was a second time secured by Fleet-Surgeon Elliott, who this time made use of a double well-carbolised hempen ligature, leaving one end hanging out of the wound. The operation was tedious, the tissues being firmly matted together. The peritoneum was with difficulty detached, and twice unavoidably opened into; vomiting occurring, with escape of small intestine and omentum. The ligature did not separate until the 4th of January, and the wound then closed. For a few days from the 19th of December there were grave typhoid symptoms, with local erysipelatous action. The pulsation ceased from the date of operation, and the sac became consolidated, being firm and of the size of a walnut when discharged to light duty on the 2nd of April. There was, however, great weakness and bulging of the abdominal wall over the site of the cicatrices.

He was employed as a cook in the provost cells, and remained at duty until the 11th March of this year, when he was admitted, and remained under treatment until the 27th March, for bronchitis; no further symptoms being noted by Staff-Surgeon Fisher, R.N., under whose care he more particularly was.

On the 23rd June he again applied for relief, having, as it has been subsequently ascertained, suffered from pain in the left shoulder and arm, with gradually increasing dyspnœa. On admission, this was urgent; the respiration loudly crepitant, with sonorous rhonchus over the whole chest, particularly over the upper portions; the heart-sounds were scarcely audible, and there was loud churning over the upper portion of the sternum; the pulse was excessively feeble and frequent; the face livid, with coldness of the extremities. No pulsation was visible over the sternum or the neck; the venous system was, however, engorged. Decubitus was found to be most comfortable on the side in a semi-recumbent position. Beef-tea, port wine, brandy, mixtures of ammonia (carbonate and chloride), squill, ether, ipecacuanha, &c., were given to arrest expectoration; the sputa being viscid frothy mucus, and latterly slightly purulent. Locally, turpentine and simple fomentations, poultices, and a blister to the left side. The radials were synchronous. On the 24th a gritty pericardiac friction was detected over the heart's apex. The dyspnœa became increasingly urgent until death, on the 29th June, at 1.50 A.M. Pain was never complained of, but to another patient he said that "he could almost reach something in his throat with his finger which seemed to prevent his breathing." There was never any dysphagia.

Post-mortem examination, June 30th, 11 A.M. — Body attenuated; rigor mortis present. On removing the sternum a large aneurism of the ascending aorta was disclosed, the anterior wall being closely adherent to, and in part formed by, the sternum, from a point level with the lower border of the first to midway between the third and fourth cartilages, the bone being in part eroded. The aneurism was 4½ in. + 4 in. in diameter, extending to and involving ¾ in. of the innominate artery anteriorly, and inferiorly overlapping the base of the heart. On opening it up, a large yellow fibrinous clot was found nearly filling it, and lying in black coagula, which further extended through a small valve-like rupture at the left base of ⅓ in. into the pericardium, the heart being also encased in it. On the right side the sac was found to be thickened to ½ in. by layers of fibrin, but on the left was thin; at the back of the aneurism, and apparently almost lying in it, from the walls overlapping on either side, was the aorta, with an oval opening of 1½ in. in length by ⅝ in. transverse diameter, the edges rounded and indurated, giving almost the idea of the upper open end of the larynx. The heart was contracted and healthy, with a thin covering of fat, and the valves normal; about 4 oz. of sanious serum escaped from the pericardium on opening it up, and the clot there weighed 8 oz. The lungs were congested, but healthy in structure, abundant sanious frothy mucus welling out on section. The left division of the trachea appeared rather small. The aorta from the heart to the cœliac axis was unduly dilated, particularly at the latter point; and, on section, patches of atheromatous change were found, but no ossific deposit.—Abdomen: Viscera healthy; the liver slightly nutmeg in character, weighing 3 lb. 10 oz. A portion of the small intestine and two loops of omentum were found firmly adherent to the abdominal wall at the seat of operation. The left internal iliac was considerably smaller than the right, and obliterated about 2 in. from Poupart's ligament. The internal iliac correspondingly increased in size, the collateral circulation being carried on by it. From the point of ligature the artery could be traced as a cord to the aneurismal sac in the groin, which was firm, of the size of a small walnut, and filled by a firm, dark, fibrinous clot, which was readily enucleated, the artery becoming pervious almost immediately below. The aneurism involved and occluded the "profunda" at its origin; the circumflex was enlarged, and carried on the circulation with it.

Walmer.

OXALURIA.

BY JAMES REOCH, M.A., M.B.

ONE of the most important questions connected with oxaluria is whether oxalate of lime may originate in the urine some time after emission, by decomposition of one of the urinary constituents. The importance of this view is evident, for if oxalates can form *de novo* in the urine itself, it will be difficult to regard them as of any pathological significance. In some preliminary experiments on this subject, some urines were kept for three or four days before filtration, and then allowed to stand for a few days longer. In many of these cases beautiful envelope-shaped crystals were seen, which, from their size, could not possibly have passed through the filter; but oxalates were not always present—indeed in not more than half the cases; while the urine invariably decomposes, and always contains uric acid and mucus. This difficulty appearing to form an insuperable objection to the decomposition theory, it was only left to suppose that oxalates were present in some of these urines, but were very slowly deposited, while in others they were absent; and this seemed the more probable, because in some of these cases the oxalates were accompanied with uric acid, which no one supposes to be formed in the urine itself, and which must therefore have been formed by slow deposition. To test directly between the slow deposition and decomposition theories of the formation of oxalates, it seemed probable that if a series of urines were kept for some time without filtration, oxalates might be found in a certain proportion of cases which may be called the normal proportion; but if the urines were kept for one, two, or more days before filtration, and then allowed to stand for the same period as before, oxalates would be found in a less proportion of cases if they were originally present but only slowly deposited, while they would be found in a larger proportion if due to decomposition, partly because they were kept much longer, and partly because the decomposition of urine is much more rapid during the second week than during the first. Accordingly, 48 specimens of "urina sanguinis," approximately consecutive from the same individual, were divided into eight series of six each. The first series was allowed to stand for seven days without filtration; the remaining seven series were filtered at periods varying from one day to seven after emission, but all were allowed to stand for seven days after filtration like the first series. Each urine was then examined microscopically; nine or ten preparations were made of the scum at the top, three of the body of the urine itself, and twenty to forty of the precipitate at the bottom; where oxalates were not readily found the examination was much more prolonged. The results are expressed in the following table:—

No. of urines.	No. of days kept before filtration.	No. of days kept after filtration.	No. of times oxalates were found.
6	0	7	6
6	1	7	5
6	2	7	5
6	3	7	4
6	4	7	3
6	5	7	2
6	6	7	2
6	7	7	2

It appears, then, that with increasing the time that a urine is kept before filtration, the probability of finding oxalates afterwards is much diminished, and not only so, but the number of crystals found is also much diminished, for while in every specimen of the first series hundreds of crystals were found, in the last series only two gave oxalates, one giving three crystals in about fifty-five preparations, and in the other eight crystals were the outcome of seventy-one examinations. The same thing holds good, as a general rule, of the other series; so that it may be laid down as a law that while oxalates may appear in urine as long as a week after emission, yet in their formation they follow the course of slow deposition, and not that of decomposition. Moreover, in none of the above cases was there noticed under the microscope any association between the oxalates and epithelial cells or mucus-corpuscles, the two most constant constituents of mucus; scores of oxalates might be seen in the field at once, but never any imbedded in an epithelial cell or mucus-corpuscle; nor was there any relation between the oxalates and uric acid observed, for while often present together, as often one only was to be found.

Again, some urines were examined which had been kept for a long time; they had been filtered on the day of emission, and then allowed to stand, three of them for two years, and four of them for nine months. Nine or more examinations of the precipitate from each of these were made, and yet no trace of oxalates was found in any. In some further experiments where oxalates were produced in large quantity by adding some oxalic acid to urine, many crystals were noticed at first, but after six weeks they appeared to be much fewer in number, at least in some of the specimens. It appears probable, therefore, that oxalate of lime, so far from being a product of decomposition in the urine, is itself decomposed.

It is often urged in favour of the view that oxalate of lime must arise by decomposition, that it is a salt which is insoluble in water and in urine. More exact experiments, however, show that this is not the case. Storer, in his "Dictionary of Chemical Solubilities," gives its solubility in water as $\frac{1}{500000}$. No doubt this appears small, but oxalates are never recognisable without the microscope, and seldom appear much larger than a blood-corpuscle. Supposing, therefore, that the specific gravity of an average crystal is equal to that of a cube of water $\frac{1}{3000}$ of an inch in the side, then, since cubes are to one another as the cubes of their sides, it follows that a cubic inch of water would be equal to 27,000,000,000 of these crystals, and would therefore, according to Storer, dissolve 54,000 crystals; 10 oz. of water would therefore dissolve 1,000,000 of these crystals; while we do not often find in urine a much larger proportion than this. And further, some direct experiments show that urine can dissolve a certain quantity of oxalate of lime, for some urine being put into a series of test-tubes, a small quantity of oxalic acid was added to all but one. After three days they were filtered through a double filter, and allowed to stand for seven days longer. Large and well-shaped crystals were noticed in nine out of eleven of these cases, while none were observed in the original urine. Again, where some urines had stood over oxalic acid for a week, and were then filtered through a double filter, after another week no oxalates were found in the original urine, but were found in four out of the lower six of the oxalic series, though not at all in four to which a large excess of oxalic acid had been added. From these experiments it appears that the urine had dissolved some of the oxalate of lime, which it had been compelled afterwards to deposit, most probably from the advancing alkalinity. In discussing the solubility of oxalate of lime, however, the greatest attention must be given to alcohol, which is by far the most important substance in this connexion. Alcohol and water differ very widely in their mutual relations to bodies dissolved by either; thus, while both alcohol and water readily dissolve the salts of the alkalies, water dissolves the salts of the alkaline earths in less proportion, but alcohol scarcely at all. This is readily shown by rubbing up some phosphate of lime in a mortar with some water and a few drops of H Cl. On filtering, there results a clear solution of the acid phosphate of lime, but on adding alcohol or rectified spirit to this there is an immediate precipitate. Now, if oxalic acid or oxalate of ammonia is added to chloride of calcium, we have in either case an immediate precipitate of oxalate of lime, because oxalic acid has a greater affinity for lime than hydrochloric acid, and the resulting salt is very little soluble in water; but if either of the reagents be gradually diluted, we arrive at a point when the precipitate does not appear at once, but takes some minutes to form, and is only faint at the best; and if just at this point we step in with alcohol we shall find the precipitate much more quickly formed. The most striking way of proving this is to add one or more drops of a 1 per cent. solution of oxalic acid to a test-tube containing ordinary drinking-water; this generally contains enough of lime salts to give a faint precipitate with oxalic acid after some time, but on adding a drachm of rectified spirit the precipitate appears at once. Again, if these various oxalate of lime precipitates be examined microscopically, it will be found that where the solutions are concentrated the precipitate is finely molecular, but with greater dilution it is granular, and with still greater its various forms may be ranged under the envelope shape; the latter is therefore the result of greater dilution, and consequently takes more time to be arranged in a crystalline form. Therefore, when $CaCl_2$ is added to a watery solution of oxalic acid, you pass quickly by dilution from the molecular to the crystalline condition; but if spirit has been added, the precipitate is much more commonly molecular because much quicker in appearing. Applying these facts to the urine, let a little rectified spirit be added to some urine in a test-tube, and an immediate white precipitate appears at the place where the two liquids meet. According to the views above enunciated, this precipitate consists mainly of earthy salts soluble in the urine, but much less soluble in alcohol; and, if the test-tube be well shaken, a permanent turbidity results.

(*To be concluded.*)

CASE OF
POISONING BY LIQ. STRYCHNIÆ (P.B.); RECOVERY.

By J. BROWN SIM, M.B., L.R.C.S. EDIN.

ABOUT 10.30 on the night of the 1st of March I was summoned by Dr. Huthwaite's assistant to see a nursemaid in their service, who had been seized with symptoms of poisoning by strychnia. He informed me that she had shortly before come into the surgery and complained to him of feeling ill, and asking to be made sick. Knowing she was hysterical, and supposing this to be an attack coming on, he administered a dose of ipecacuanha wine. He then noticed her jaws becoming fixed, suspected the cause, and at once sought for help. Hastily calling in a woman to be with her, he then found her on the floor, with the body arched (opisthotonos).

On arriving, I found the whole body rigid, the jaws firmly fixed, the head jerked backwards, the face of a dark-purple hue, and the pupils dilated. I at once proceeded to use the stomach-pump, but found it impossible to pass the tube through the teeth, which no amount of force could separate. She was then rapidly put under the influence of chloroform, which exerted so beneficial an action upon the spasms that we were very soon able to pass the tube into the stomach. This organ was then thoroughly washed out several times with tepid water, and brandy and strong coffee injected. As symptoms of depression frequently showed themselves, the pulse was closely watched, and whenever depression appeared brandy was freely given through the stomach-pump. The temperature in the axilla was 95·2°. The spasms came on at intervals varying from two to five minutes, but always ceased on the administration of a little more chloroform. We were joined in the course of the night by Dr. Huthwaite; and, as he agreed with the treatment adopted, it was continued. The spasms were confined, after the administration of the chloroform, to the face, trunk of the body, and the upper extremities; only once did the lower limbs show any sign of spasm. They became gradually milder in intensity until about 4 A.M., when we ceased the administration of the chloroform.

On recovering consciousness she was at once questioned as to what she had taken, when she replied "strychnia." On being asked where she had got it, she said "from the surgery"; and she knew it was strychnia because there was "liq. strych." on the bottle.

The story obtained from her afterwards was that, thinking herself in the way, she had determined to commit suicide. At a quarter past 10 she had taken about a mouthful of the liq. strychniæ, and almost directly afterwards felt oppression at the chest and difficulty of breathing. She then got the draught already mentioned, but could not be sick. She suffered acute pain throughout her body, and in the intervals of the spasms wanted to speak, but could not. Her intellect must have remained clear up to the time she was put under the influence of chloroform, as she could tell all that had been said and done up to that time.

From her statement, and from the quantity missing from the bottle, it is calculated that she must have taken a dose of not less than six drachms of the liq. strychniæ of the British Pharmacopœia—equal to three grains of the alkaloid. She made a good recovery, and is now quite well.

A fact worthy of record in connexion with the case is the necessity of using *pure* chloroform. We had unfortunately run out of our supply of chloroform, and, having obtained some from a neighbouring druggist, to our consternation, found that we could not subdue the spasms, and that they were gaining in intensity. Another specimen, made by Duncan and Flockhart of Edinburgh, having been obtained, the spasms were at once brought under complete control. The patient was thus under the influence of chloroform for five hours, and about eight ounces of that agent were used.

ST. BARTHOLOMEW'S HOSPITAL.

VESICAL CALCULUS IN A BOY EIGHT YEARS OF AGE, WITH SYMPTOMS ALL HIS LIFE; LATERAL LITHOTOMY.

(Under the care of Mr. HOLDEN.)

For the notes of the following case we are indebted to Dr. James Shuter, house-surgeon.

W. H. H——, a boy aged eight years, was admitted June 14th, to Pitcairn ward. He was a small, dark-haired, badly-nourished child, with Jewish features, large tonsils, and left internal strabismus; and was somewhat deaf and decidedly *non compos mentis*. He was the survivor of twins, and had never been quite rational. He appeared to have always had pain in his penis on passing water, and had been in the habit of compressing his glans penis antero-posteriorly between his finger and thumb during micturition. The stream had occasionally been seen to stop suddenly and then to recommence. No blood had ever been noticed. He strained very much at stool and during micturition.

On admission, though he strained very much on passing water, the passage of it did not seem to cause him much pain. His urine was thick with mucus, feebly acid, and contained no albumen. The appetite was good.

June 23rd.—He was sounded, and a stone was both felt and heard. It appeared to be stationed at the left of the pubes, and could be felt through the rectum.

30th.—Since admission patient has much improved in general health. He still strains at stool, and grasps the end of the penis during micturition. He passes water more freely during the day than the night. Pulse 104; temperature 99·1°; tongue moist and white. At 1.30 P.M., when under the influence of chloroform, Mr. Holden performed the left lateral operation for lithotomy, and removed an ellipsoidal calculus, crystallised on its surface, composed of phosphate of lime, weighing 67 grains, and measuring three-quarters of an inch in its long and five-eighths of an inch in its short axis. It was lying in a small cul-de-sac of mucous membrane just to the left of the median line and close to the pubic arch. There was very little hæmorrhage. No plug was used. During the operation prolapsus ani occurred, and the patient vomited before leaving the theatre. After being put to bed respiration almost ceased. An hour after the operation the pulse was 120, the temperature 99·4°.

July 1st.—Slept well; has taken some milk and bread-and-butter. Water passes freely through the wound, none through urethra. Tongue moist and clean; pulse 120; temperature 99·4°.

2nd.—Slept well and takes nourishment. Since yesterday at mid-day there has been no water through the wound, but it has been seen coming through the urethra. The wound is clean, and there is no inflammation around. Tongue moist and clean; pulse 104; temperature 98·8°.

From this time the patient progressed favourably in every way. For a day or two he had considerable pain in the penis immediately before passing water. The wound healed gradually, and was completely healed by July 12th. No water through wound since July 1st.

19th.—Discharged quite well.

MIDDLESEX HOSPITAL.

CASES OF FISSURE OF THE ANUS.

(Under the care of Dr. Arthur Edis.)

Fissure of the anus; supposed uterine disease; division; complete recovery.—S. W——, aged twenty one, married two years; one child, aged seven months. Ever since her confinement the bowels have been very confined, often going a whole week without acting. For the last five months she has taken two to three teaspoonfuls of castor oil every morning. She experienced severe agonising pain on defecation, the pain lasting the greater part of the day, and quite unfitting her for her household duties. A medical man had been in attendance for several months, and had treated her for an affection of the womb, only lately having had any suspicion that something was wrong with the bowel, when two leeches were applied to the anus, but no examination made. The patient had been confined to bed for nearly three months. Having heard the above history, the lower bowel was carefully examined, and on passing the left forefinger a hard, exquisitely sensitive fissure on the posterior aspect was detected. As the patient was exceedingly nervous, and the examination caused much pain, a small quantity of chloroform was given, and the fissure divided by means of a blunt-pointed bistoury. Oiled lint and opium suppository were inserted, and the bowels relieved on the third day without any pain whatever. Attention to the state of the bowels caused great improvement in the general health. After the first few days the patient had no return of the symptoms, and recovered perfectly.

Fissure of rectum; supposed piles; operation; recovery.—E. E——, aged twenty-five, single, presented herself, complaining of certain uterine symptoms, together with severe pain in defecation, which had been present during the last two years. The bowels were habitually constipated, the patient frequently allowing a whole week to elapse without their acting—in fact, the pain was so severe "she never went unless she was absolutely obliged," as "the agony was so excruciating," becoming worse and worse an hour or so after the bowels acted, the pain often lasting for twenty-four hours, and the motion being streaked with blood.

On examination, a small condylomatous growth at the anterior margin of the anus was detected, which the patient stated she had regarded as a pile, and had had ointment prescribed for it, though she had never been examined. On inserting the finger per anum, a fissure was found extending up an inch or more into the bowel from the growth externally; considerable pain was complained of at the time, and the finger on withdrawal was streaked with blood.

The growth was at once removed by the aid of curved scissors, and the fissure divided along the base by means of a bistoury. Oiled lint was inserted, and a mixture of sulphate of magnesia and sulphate of iron prescribed, to ensure regular action of the bowels, a soothing lead lotion being also ordered. The pain on defecation gradually disappeared, and the patient recovered perfectly within a few weeks.

The case is of interest, as the patient had been seen by several practitioners, who treated her for piles on her own representation, without ever confirming or upsetting the patient's own diagnosis by means of an examination. She had been doctoring, on and off, for nearly the whole of the two years during which she had been suffering.

In place of confining the bowels by means of opium subsequently to the operation, as usually advised, a tonic aperient mixture was prescribed, and regularity of the bowels thus ensured.

ROYAL INFIRMARY, EDINBURGH.

LOOSE CARTILAGE REMOVED FROM THE KNEE-JOINT, ANTISEPTICALLY; CURE.

(Under the care of Mr. Joseph Bell.)

For the notes of the following case, which we had the opportunity of seeing several times during the week that the British Medical Association held its meetings in Edinburgh, we are indebted to Mr. A. J. Vanse, M.B., C.M., house-surgeon:—

William C——, aged thirty-nine, foreman in an iron-foundry, was admitted July 14th, 1875. For the last nineteen years the patient has felt a hard body in his left knee-joint, and has from time to time experienced sudden severe pain in that region. About nine months ago the joint began to swell, and since then he has on several occasions fallen to the ground from the sudden accession of pain in connexion with the knee. On July 28th Mr. Bell made an incision into the joint, with the ordinary antiseptic precautions, and removed a smooth, hard body about the size of a filbert, and at the same time a quantity of opalescent fluid escaped. The joint at the time of the operation was in a state of inflammation. A drainage-tube was placed in the wound, the lips of which were closed by catgut sutures, and the usual gauze dressings applied.

The wound was dressed every twenty-four hours for the first six days; subsequently with an interval, first of two, and then of three days, and on no occasion did the wound present the slightest trace of inflammation. The temperature never rose above 99·5°. The drainage-tube was removed on the fourth, and the sutures on the tenth day, and the wound was quite healed on the twelfth day after the operation, without the patient having experienced any pain. He was allowed to walk on the 8th, and left the hospital on the 12th of August quite well.

DEVON AND EXETER HOSPITAL.

THREE CASES OF ANEURISM SUCCESSFULLY TREATED BY DIGITAL COMPRESSION.

For the notes of the following cases we are indebted to Mr. Edward J. Domville, late house-surgeon.

Case 1. *Aneurism of femoral artery; digital compression; cure.* (Under the care of Mr. A. J. Cumming.)—John C——, aged thirty-eight, in receipt of an army pension, but working as a day labourer, was admitted into hospital on Oct. 30th, 1873, having a pulsating tumour on the front and inner side of the left thigh, over the position of the femoral artery as it passes through Hunter's canal. The patient could not account for its existence, and could not remember any blow or strain. He had only noticed the swelling for five or six weeks, and only quite recently had felt the pain in it, for which he now sought relief.

Digital compression was applied to the femoral artery in the groin by relays of students on the day after admission, and kept up for twenty-four hours without producing any permanent effect, although as long as the pressure was applied the pulsation ceased entirely, and the tumour decreased in size.

After a week's interval of rest in bed, the same plan of treatment was again carried out for seventy-two hours, and complete success was the result. The patient was discharged cured on Dec. 2nd, 1873, and has since been continuously able to follow his occupation.

Case 2. *Popliteal aneurism; failure of flexion; cure by digital compression.* (Under the care of Mr. A. J. Cumming.)—George G——, aged forty-nine, was injured in the wrist twenty years ago, and was in consequence invalided from the army with a pension, but was not sufficiently ill to prevent him working as a gardener. In September, 1874, while at work he felt a sudden pain under his left knee, which continued, and was in a few days followed by a "beating sensation," but he could not perceive any swelling. In November, the leg began to swell by day, resuming its size after a night's rest. He could give no history of a blow, and was not subject to any strain when he first felt the pain. No palliative treatment had been adopted before his admission into hospital in January, 1875.

On admission, the left popliteal space was found to be occupied by a pulsating tumour, over which the skin was very tense, but not discoloured, although the superficial veins were enlarged. The pulsation was distinct, both laterally and eccentrally, but was readily controlled by pressure on the femoral artery. The circumference of the limb over the centre of the patella was 15½ in.; and of the right limb, 13¾ in. There was a systolic aortic bruit heard also in the tumour, but otherwise the patient was in good health.

On the 16th January digital pressure was applied to the femoral artery in the groin for fifteen hours, when it was found that pulsation had ceased. After an interval of two hours, as it was supposed that a return of pulsation threatened, pressure was reapplied for three hours, making a total of eighteen hours.

Extreme flexion was at first tried for this case, but the pain caused was so great that the patient was unable to bear it for any length of time. To relieve the pain caused by the pressure chloral hydrate was used, the injection of a sixth of a grain of morphia having previously caused intense headache, with great depression.

The patient was kept under observation for three weeks, and then discharged cured, no further treatment having been required.

Case 3. *Popliteal aneurism; digital compression; cure.* (Under the care of Mr. Bankart.)—William H——, aged twenty-eight, labourer, retired from the army in 1870, after seven and a half years' service, and is now in the militia reserve. In February, 1875, while carrying a heavy bag of manure on his back, his leg gave way suddenly, causing him great pain, and putting his hand down he felt a "beating" under his left knee. The pain went away on his walking about, but returned when he lay down.

On admission in April there was found to be a pulsating tumour in the left popliteal space, pulsation being distinct in all directions. The skin was not tense, nor were the superficial veins enlarged. The leg below the swelling was of its natural size, but over the tumour the difference between the circumference of the two limbs was one inch.

On April 24th digital pressure was applied over the femoral artery and kept up by the house-surgeon and relays of students for sixty hours, and at the end of this time, although the tumour appeared smaller and more firm, the pulsation was scarcely lessened.

After a week's interval of rest in bed, the patient insisted on going home to see his wife, who was ill, but returned after two days' absence, having suffered a good deal of pain, but the tumour had not perceptibly increased in size.

Digital pressure was again applied as before, and after six hours pulsation ceased. The pressure was, however, kept up for thirty hours more, and subsequently applied for short periods as a precautionary measure, but there was no return of the pulsation, and the man was discharged cured at the end of a fortnight.

It is worthy of note, as a coincidence, if nothing more, that all three cases were army pensioners; although in the first case the amount of actual service was limited to a two years' preparation for the review at which he was injured.

The plan adopted in all three cases was to set two students at a time on duty for two or four hours, each to apply pressure on the artery for ten minutes at a time, while the other, keeping watch with his hand on the tumour, gave warning of a return of pulsation due to any slackening of effort. As the staff of helpers was limited, these efforts were supplemented by the occasional application of the horse-shoe tourniquet. If it is fair to judge from the numerous cries of warning given by the students on watch in almost every instance, it may be that some share in the cause of failures to cure after many hours' application, in cases where each person was expected to keep up pressure for an hour or more at a time, must be considered as due to a relaxation of effort on the part of the individuals compressing.

In conclusion, it may be added that both patient and compressor found considerable relief from the occasional use of a small tourniquet pad instead of direct pressure with the thumb or fingers. Its use also avoided the irksomeness caused by a nervous search for the artery by first-year students, and which the patients are not slow to observe.

NORTH RIDING INFIRMARY, MIDDLESBOROUGH.

CASE OF LOOSE CARTILAGE IN KNEE-JOINT; REMOVAL ON ANTISEPTIC SYSTEM; RECOVERY.

(Under the care of Dr. W. J. Williams.)

For the following notes we are indebted to Mr. W. Stirling Anderson, house-surgeon.

Patrick L——, aged twenty-two, was admitted into the North Riding Infirmary, on 11th August, 1874, with a loose cartilage in right knee-joint. About four years ago patient was working on a night shift, and having occasion to be on his knees, found on rising to the erect posture that he could not straighten his right leg. The leg was perfectly free of pain as long as it remained in the semiflexed position, but any attempt to straighten the limb was attended with great pain. Some swelling of the joint took place, but subsided in some little time, leaving him the perfect use of the limb. Eighteen months afterwards he became subject to excruciating pain in the joint when walking, resulting after complete extension of the limb. The pain continued for nearly ten minutes, during which he could not attempt to straighten the limb without suffering great pain. Shortly afterwards he found a little lump on the inside of the joint, at the lower and inner border of the patella, which disappeared on pressure. He continued in this state till the end of last month, but was then forced to put himself under treatment as the sudden seizure of the pain when working (at a blast furnace) placed him in jeopardy of some accident from the consequent inability to use his right leg. After an ineffective trial to remove the loose body, he applied for admission to this hospital.

At noon on August 26th, Dr. Williams proceeded to remove the loose body.

The joint was quite natural in appearance except below the patella, where there was some little thickening, which, patient says, was the result of an accident he met with when a child. On examination, no loose body could be found; but after patient had walked once or twice across the floor, a small body, of the apparent size of a sixpence, was detected on the outer and anterior part of the capsule.

The leg was bent on the thigh to assist the operation in keeping the loose body in its place, as it had a tendency to glide in between the articular surfaces of the tibia and femur. Chloroform was dispensed with. The skin over the joint and vicinity was thoroughly washed with an oily solution of carbolic acid (1 to 10). The knee, as noted above, was flexed; the fingers of an assistant pressing from below kept the loose body in position. Under a spray of carbolic-acid lotion (1 to 40), Dr. Williams made an incision two inches in length, its lowest point being an inch higher than the position in which the loose body was felt. The part of the capsule over the body was reached by the finger through the wound; the body was seized with a tenaculum and pulled out after the capsule had been opened. This part of the operation was somewhat protracted by the tendency of the loose body to shift about, even though pressed upon from below. On examination, the loose body proved to be a flat piece of cartilage, about the size of a large bean.

All the steps of the operation were conducted under the spray, the fingers of the operator and assistant, as well as the instruments used, being washed in carbolic acid lotion (1 to 40). The limb was extended, and the wound (the lips of which were not brought together by sutures) dressed with a small piece of protective oiled silk, overlapped very freely in all directions by a piece of antiseptic gauze folded (8 plies) according to Professor Lister's directions. The limb was kept in the extended position by a piece of Gooch splint applied posteriorly.

August 26th.—9 p.m.: Patient is very well. Indeed there is no difference in him, when contrasted with his state before the operation, save that he is confined to bed. Finds the extended position of limb very irksome. He has taken his dinner, tea, and supper as usual, and relished them. Does not complain of the least pain in the joint. Says there is a little soreness at the wound. Temperature 98·4°; pulse 60.

27th.—10.30 a.m.: Had a good night. Has taken his breakfast as usual. At present he does not feel the slightest uneasiness in any part of the limb. Temperature

98°; pulse 56; tongue natural.—Noon: The wound dressed under the spray. There has been some little sanguineous discharge, but the wound itself is perfectly free from the slightest irritation. Dressed as before.—9 P.M.: Patient says there is not the least uneasiness in any part of the limb. Has suffered from diarrhœa this afternoon. To have pill of lead with opium. Temperature 97·8°; pulse 52.

28th.—9.10 P.M.: Patient's temperature this morning was 98·4°; pulse 52. He had quite recovered from the diarrhœa. The bandage over the Gooch splint was taken off to see if there was any discharge, but there being none, the dressing was not proceeded with. To-night he is, as in the morning, perfectly well. Temperature 97·4°; pulse 52.

29th.—9 P.M.: This morning patient continued as at last note. In the afternoon the dressing was changed under the spray. There was some slight sanguineous discharge staining the gauze, but nothing more. The wound was filled up with clot, and its edges were quite natural, being free from the slightest irritation.

Sept. 1st.—Wound dressed to-day. No appearance of granulations; the original clot undergoing organisation, filling the gap. Slight lympho-sanguineous discharge, but not more than ten drops. General health all that could be desired.

5th.—Wound dressed as before. No granulations, and no purulent discharge. Cicatrisation going on well.

10th.—Wound almost healed. Still no granulations.

15th.—Wound healed and cicatrix strong.

After the last dressing patient was allowed to walk about, which he could do perfectly, there being no stiffness nor uneasiness in the joint. He returned to his heavy labour, finding himself fit to engage in it.

Reviews and Notices of Books.

The Management of Infancy and Childhood in Health and Disease. By HOWARD BARRETT, M.R.C.S., late Surgeon to the Poplar Hospital. London: Routledge and Sons.—This is a sensible book, and may be safely recommended to those who desire information on the subject of which it treats. It does much to supply the lack of education in physiological and medical matters which is so painfully apparent in most parents. Not the least merit of it is that several chapters are occupied in discussing, in a general way, the hygienic management of children. The author gives, in the latter half of the book, good clear accounts of particular diseases, medical and surgical, and their treatment, which will be found very useful for people out of the reach of doctors; but the first half of the book is devoted to such questions as Nursing, Diet, Ventilation, the Influence of Light, Vaccination, Disinfection, &c.—a careful study of which on the part of parents will be rewarded with healthy children and the infrequent need of doctors' help.

Italian Alps. Sketches in the Mountains of Ticino, Lombardy, the Trentino, and Venetia. By DOUGLAS W. FRESHFIELD. London: Longmans, Green, and Co. 1875.—The author in his preface apologises to the public and to his friends for this work; but he need not have done so. It fills up a gap in the descriptive history of Alpine scenery, about which English readers have hitherto found no information in their own language except in guide books. The Italian Alps are very little known to the ordinary British tourist, and though we have had enough and to spare about mountaineering adventures, described cleverly, badly, and indifferently, the reader will find here a pleasant account of "fresh fields and pastures new." The exquisite valleys round the head of Lago Maggiore, the mountains of Val Masino and Val Livigno, the Punta Trubinesca and the highlands of Lombardy, and the Trentino are not as yet overrun by Mr. Cook and his satellites. This book is admirably got-up, with maps by Stanford, and some pleasing engravings. Some of the subject-matter has already, in a fragmentary way, appeared in *Fraser's Magazine* and the *Alpine Journal.*

Snioland or Iceland. Its Jokulls and Fjalls. By WILLIAM LORD WATTS. London: Longmans and Co. 1875.—This is evidently a book of the period, though a far less ambitious production than that last noticed. Mr. Watts has published, in the form of a daily journal, particulars of an excursion to Iceland, commenced in June of last year. It is not, perhaps, generally known that that island is well within the limits of a six weeks' holiday; the voyage is short (about six days, including a stop at Faroe), and the climate very healthy. The author does not aim at elaborate descriptive writing, and is often prolix, giving particulars that few would care to read, but the book would be useful to any intending excursionists northwards, and is illustrated with some middling photographs.

The Wines of the World Characterised and Classed. By HENRY VIZETELLY. London: Ward, Lock, and Tyler. 1875.—This is the cheapest shillingsworth that we have seen for a long time. Mr. Vizetelly was one of the wine jurors at the Vienna Exhibition of 1873, and the book before us is, in fact, a revised and amplified version of the reports on wines and beers drawn up for the Commissioners. The wines of France and Algeria, Germany, Switzerland, Austria, Hungary, Russia, Spain, Italy, and, indeed, those of all other countries, including our colonies, are here described *seriatim,* and there is a concluding critical chapter on the beers of Europe, which we recommend as a practical guide to those of our readers who patronise malt and hops in preference to more luxurious beverages.

Sex in Industry: a Plea for the Working Girl. By AZEL AMES, jun., M.D., Special Commissioner of Investigation, Massachusetts Bureau of Statistics of Labour, &c. Boston: James R. Osgood and Co. London: Trübner. 1875.—This little book is the outcome of an inquiry made by order of the Massachusetts Statistical Bureau on the influence of homes and employments upon health. The marvellous rapidity with which digital operations are performed by girls in factories led to special inquiries as to how far the sexual status was affected, and detailed facts are given in this book as the result of these inquiries that must be very interesting to those of us (and they are many) in this country who want to solve satisfactorily the vexed question as to the proper field for feminine labour. Standing for many hours, counting, telegraphing, and many other mechanical operations in which women are now employed in England, but far more extensively in the States, are all declared, and, according to the author, proved, to be positively injurious, and in many cases utterly fatal to the health of the girls engaged therein. Many of the deductions drawn are, however, as we think, much exaggerated; but the book is thoughtfully written, is short, and worthy the attention of all who are collecting opinions, facts, and statistics on this important subject.

A Primer of the English Constitution and Government. By SHELDON AMOS, M.A., Professor of Jurisprudence, University College, London, &c. Second Edition. London: Longmans, Green, & Co. 1875.—This small work is intended, as we suppose, to be called "legislation made easy," inasmuch as it professes to teach the law to the laity in the same sort of way as popular medical handbooks attempt to teach to non-professional persons the science of the prevention and cure of disease. We do not profess to review a book so entirely out of our field of work; but there is a great amount of interesting information in this volume, although we are disposed to think that, with regard to both law and physic, a little knowledge is a dangerous thing. Law is never likely to become, in any sense, a popular science.

REPORT
OF
The Lancet Commission
ON THE
SANITARY CONDITION OF OUR PUBLIC SCHOOLS.

◆

MARLBOROUGH.

Of the schools as yet visited by The Lancet Commission, Marlborough decidedly takes the lead with regard to the excellence of its sanitary arrangements. We have therefore selected this school for our first report, as it so nearly approaches the standard we laid down in our introductory articles as to what a school should be. The excellence of Marlborough in this respect is chiefly owing to the medical officer, Dr. Fergus, who for twenty-six years has been attached to the school, and who has devoted his whole time to the duties of the post; he has moreover been admirably seconded by the school authorities. Marlborough is a proprietary college, and at the present time contains about 560 boarders—viz., 380 in the school buildings and 180 in the out-boarding houses. The pupils are chiefly drawn from the professional classes. The school buildings consist of an old brick mansion, formerly the famous Castle Inn, and some more recent buildings, which together form a somewhat irregular mass, but well open on all sides to the air. It is situate on the old Bath road, and the town terminates abruptly at the college entrance. The out-boarding houses are some little distance from the college, on the Bath road, and consequently are still further separated from the town. The college, the town, and the boarding-houses drain into the river Kennet, but all have a distinct system of sewers; the town outlet being a considerable distance down the stream, below the outlets of the college and the boarding-houses. The college drains unite, at a point some hundred yards distant from the college buildings, to form a main sewer, which, about two hundred yards further, opens into three large tanks, which collect the solid excreta, the liquid overflow alone passing into the river. These tanks are cleaned out during the holidays, and they are more than sufficient for the requirements of the school. They are well ventilated, and no unpleasant smell can be perceived when standing over them. The advantage gained by intercepting the solid excreta is that no deposit takes place in the bed of the river opposite the college, which might silt up and become exposed and offensive during the dry months of the year. The means of flushing the college drains are very perfect. An immense volume of water can be poured into them by means of hydrants provided in all parts of the building for the purpose of extinguishing fire. During term time the medical superintendent personally superintends the process, and sees that it is regularly and efficiently carried out. The drainage of the boarding-houses is equally complete and entirely separate from that of the town. The college has a water-supply of its own. Its source is a deep well sunk in the chalk; the water, though somewhat hard, is excellent in quality and abundant in supply, and there is no possible chance of its becoming contaminated either at its source or in the course of its distribution. The service is constant, and carried to all parts of the building, and cisterns are attached to all the waterclosets.

At Marlborough the general plan is to have sitting-rooms for the preparation of studies; in some of the new boarding-houses there are single studies for the senior boys, and dormitories. The size of some of these dormitories is the one objection we have to find with the Marlborough system. In our introductory remarks, whilst giving preference to the dormitory over the double system—i.e., union of study and bedroom,—we stated that the number in the dormitory should be limited, certainly not exceeding fourteen. Our reason for this was, that while the numbers in a dormitory are a protection against immoral practices being carried on, yet an increase of numbers is dangerous in a sanitary point of view, as giving greater scope to the introduction of zymotic disease. In small dormitories the case is otherwise; in a ward of fourteen, if a case, say of scarlet fever, is introduced, it is easy to procure effectual isolation without materially interfering with the school work, but in a large chamber this is impossible. We believe this to be the secret of the outbreaks of scarlet fever that attacked Marlborough some few years ago, and our opinion is strengthened by the report of Dr. Bristowe. That gentleman found the dormitories in question, at the time of his visit, overcrowded, and he advised a diminution of the numbers. In all other respects his report of the school was most satisfactory, and we think it right, in justice to the authorities, to quote some of it at length:—

"From the statistics of the sanitary state of the boys which were placed before me, it seems that, but for outbreaks of scarlet fever, which have been exceptionally frequent during the last few years, their health has been remarkably good. There is no evidence, so far as I can learn, of the occurrence of disease traceable either to emanations from the soil, or to defective drainage, or to impure water, or directly to overcrowding or imperfect ventilation. The occasional introduction of the poison of scarlet fever into a large establishment is an accident which no precautions can wholly avert, and I do not see how you can prevent it. The spreading of the disease, however, is promoted by various adverse conditions, some of which it may be in our power to obviate. Thus it is promoted by overcrowding and insufficient ventilation, by incomplete isolation of the sick, and by the concourse of a large number of persons who are not protected by having previously suffered from the disease. The first two of these conditions, so far at least as in your case they seem to me defective, I have already criticised; the last condition is obviously a very important one, but it is of course entirely beyond your control. But I must acknowledge that the marvellously low mortality which your statistics show, and the complete immunity which there has been from consecutive dropsy, are high testimonials in favour of your general sanitary state, and of the excellent care you take of the sick. I do not presume to give you any advice in regard to the hygienic, or other treatment, of your scarlatinal cases, for the simple reason that in every respect their treatment appears to me to be perfect; and I cannot resist this opportunity of saying how much I was struck with the numerous niceties of hygienic arrangements which prevail, not only in the infirmary and sanatorium, but throughout the college."

Since Dr. Bristowe's report (1868) the bedroom accommodation has been considerably increased by the erection of new buildings and boarding-houses; the new sleeping rooms approximate more nearly to the standard laid down by ourselves, and the school has not experienced any fresh outbreak since that time. The senior forms are allowed to go into the town on all days except Sundays; the remainder are limited to the High-street; and, in case of any epidemic occurring in the town, the privilege is forbidden on the representation of the medical officer.

The dietary is sufficient and abundant; half an hour is allowed for breakfast and tea, and forty minutes for dinner. No boy is allowed to leave the hall till *licet* has been called, thus preventing fags been sent off before the meal is completed. On days when "big game" or "house matches" are played, extra refreshment is supplied to such members as have been playing. All the boys dine in the common hall, and the house master sits at the head of each table, and the head master presides over the whole; an excellent arrangement, which allows any defect of service to come under immediate observation.

With regard to the sanitary arrangements of each house, the waste pipes from the baths, lavatories, &c., are thoroughly trapped, and no communication with the drain is possible, and in nearly every instance separate pipes convey the waste water away, and the wastes do not enter the soil pipes of the waterclosets whenever it is possible to have a separate conveyance for them. The rule of having every pipe carefully trapped has been enforced throughout the college, and when there is any fear of the traps being dried in hot weather means are adopted for refilling them. The closets are separate; those out of doors arranged in sheds, whilst a sufficient number are provided on each staircase for night use; they are all well ventilated, and free from smell. The urinals are of slate, and flushed with water.

The sanatorium for the reception of infectious cases is situate some little distance from the school; it is commodious and well ventilated. The apparatus for baking the clothes and bedding of the patients is admirable and convenient, any quantity of clothes and bedding being heated in a remarkably short space of time. The ordinary sick-house is quite distinct from the sanatorium.

Medical supervision is carried out to its fullest extent. The medical officer devotes his whole time to the interests of the school; he is constantly mixing with the boys. On entrance each boy is required to fill up a form, signed by the parent, stating age, date of admission, school number, specifying what contagious disease he has had, together with any peculiarity of constitution that should be noted by the medical officer, such as liability to colds, if born in India or within the tropics, hernia, headache, rheumatism, &c. It is a rule that every boy who is not in school must be in the sick-house, or have leave to be elsewhere, so that all boys who complain even of the most trivial ailment are at once seen by the medical officer, and prompt treatment and isolation secured in case of infectious disease manifesting itself. Moreover, all malingering is thus checked. Marlborough has the reputation of being a working school; indeed, nearly all the boys are dependent on their own exertions for their future prospects in life, consequently the amount of work required is above the standard. Dr. Fergus assures us, however, that cases of breakdown are exceptional, and this must be attributed to his constant supervision, any apparent overtask coming at once under his eye, and a check being placed on the studies. The same wholesome supervision is exercised in the playground. At the time of our visit we entered the gymnasium, and Dr. Fergus at once recognised a boy who was, in his opinion, taking too much out of himself, and said, "I shall have to give him a caution." This frequent contact of the medical officer with the boys is most beneficial, for it teaches him to recognise at a glance the particular strain injurious in a given individual, and to check at once the mischief that may arise from too long or severe continuance of the same. Only a medical officer entirely and devotedly attached to the work could acquire such knowledge, and we are sure that our large public schools would not only be doing their simple and obvious duty, but also consulting their own interests, by making it worth the while of cultivated medical men to undertake this special branch. One other judicious regulation we must notice. In case any boy is found unfit for school life, the house master and the head master are consulted, and the boy sent away for a term or so until his health or strength allows him to return. Dr. Fergus has found that many delicate boys suffer during the spring months, a time trying to the health at all schools; in these cases he allows them only to keep the summer and autumn terms. This, while causing no real loss of time, promotes the general health, and permits the boy, who otherwise might have broken down altogether, to go successfully through his school career. It has been suggested to us that Marlborough, lying as it does in the hollow of the chalk downs, is damp. At the time of our visit we saw no indications that that was the case, though from its situation it might be somewhat flooded in wet seasons, when the water from the hills drained rapidly down into the valley; this water would, however, speedily run off. If any dampness was experienced during the autumn and winter months it might easily be remedied by increasing the surface drainage, with little expense, as far as the college is concerned.

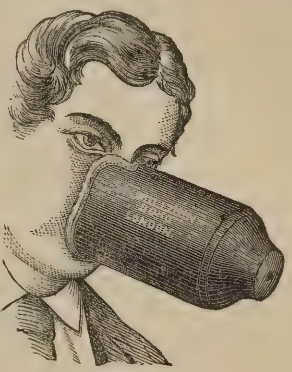
EXAMINATION IN STATE MEDICINE AT CAMBRIDGE. This examination will commence on October 5th. Candidates who pass it satisfactorily will receive certificates testifying to their competent knowledge of what is required for the duties of an officer of health. Any person whose name is on the Medical Register may present himself for the examination provided he is twenty-four years of age. Candidates for the examination are required to send their names before September 15th to Professor Liveing, Cambridge.

New Inventions.

NEW ETHER INHALER,

AS SUGGESTED BY MR. GOLDING BIRD.

THE advantages claimed for this inhaler are its simplicity and cheapness as compared with the usual ether inhalers. The waste of the anæsthetic by evaporation is reduced to a minimum by the fact that the inspired air enters by the aperture at the apex, guarded by a valve opening inwards, and the expired air passes out by that just above the nose, where there is a valve opening outwards. The mouthpiece includes all from the bridge of the nose to the chin, and is so arranged as to be practically air-tight to all faces. The instrument is light; it is lined with a waterproof material, and its edge is bound with soft leather, either of which will wash; but, if desired, a thin flannel bag carrying the sponge can be inserted, and its mouth be turned up all round outside the mouthpiece of the inhaler, and so each patient can have the advantage of a clean instrument. It is used not only for ether, but also for the mixture of alcohol (1 pt.), ether (2 pts.), and chloroform (3 pts.), for which it is admirably adapted. It is designed to embrace some of the advantages of the more elaborate inhalers, and to do away with the waste of the anæsthetic that is always caused where a sponge and towel or felt inhaler are employed.



This inhaler is manufactured by Mr. J. Millikin, of St. Thomas's-street, Borough.

MYCOSIS OF THE SKIN.

To the Editor of THE LANCET.

SIR,—During a recent examination of specimens of the "Bouton de Biskra," which Dr. E. Weber was good enough to send me—none being procurable during my visit to Biskra in October last,—I have found, in addition to the ordinary "granulation" tissue, very clear evidence of the presence of a true fungous growth. Thus, in canals which have the appearance of "lymphatics," and one of which runs alongside a "sweat-duct," there may be seen masses resembling the well-known groups of "micrococci," and, in addition, a transition from the characteristic granular substance to filaments and felted masses, which are clearly of veritable fungous character. "Conidia" seem to be given off at the ends of some filaments.

My examination has yet to be completed in other respects, and I hope to submit the results inclusive to one of our medical societies in due time; meanwhile, in order to record the present observation without loss of time—and I think it is one of considerable significance,—these few lines are forwarded for early insertion in THE LANCET, should you be able to find a place for them.

I am, Sir, your obedient servant,

H. VANDYKE CARTER, M.D.,
H.M. Indian Army.

Bombay, July 30th, 1875.

THE LANCET.

LONDON: SATURDAY, AUGUST 28, 1875.

SIR ROBERT CHRISTISON tried hard to reverse public opinion on the questions on which he discoursed so affluently at Edinburgh. But he will not succeed. We are not insensible—it is impossible to be so—to the charms of his powerful advocacy of the existing state of things. He can appeal to a long and rich experience; he has been personally identified for fifty years with the history of an illustrious University; he possesses a mind so apt and able as to be independent of particular systems, and to gather about itself all that is of the best either in systems or in men. It is natural that Sir ROBERT should be enamoured of the order of things in which he has played so honourable a part, and which to him is so rich in pleasant associations. And we are ready to admit that, if he were a fair representative of all students and all teachers, the system which he supports would do well enough, or as well as any other. But this is just what, we have to remember, is not the case. And in a clear perception of this difference lies the secret of the main answer to Sir ROBERT'S address, which, despite the length of it, is agreeable reading.

Sir ROBERT CHRISTISON goes in boldly for two things in the existing system of medical education and examination which have of late been much spoken against, as we think justly. The first of these, which alone we notice to-day, is the system of lecturing—that mode of education which addresses itself for hours together in the day over a period of three or five months to the minds of students through their mere ears. We are not persuaded by Sir ROBERT'S arguments in favour of lecturing, nor can we think that others will be so, especially those who are familiar with the way in which the courses of lectures are treated by students in Edinburgh. Sir ROBERT was famous, not only for his lectures, but for the discipline of his class-room. The most unruly student put in an appearance, with proper frequency, at Sir ROBERT'S lectures. Not only so. While he was there he was kept in order. But this result was personal, and was by no means achieved in the case of all the professors, even of those scientifically and personally respected. All sorts of different results from these were to be seen, including sleep, various games, skilful escapes from the class-room after leaving a card or answering to one's name; or that state of mental inactivity which is the complex result of sitting listening and of knowing that you will find the essence of all that the lecturer is saying in his own book. But let us note Sir ROBERT'S arguments in favour of lecturing and his illustrations in support of them. He says that systematic instruction is an essential preparation for practical study. There is some truth in this proposition. But it by no means follows that systematic statements should take the form of lectures of an hour's duration. You may have too much of a good thing, and you may easily have too much of systematic statement. And the strong set of opinion at present is in favour of the view that the lecturing system gives too much systematic statement and too little objective teaching. Sir ROBERT alluded, but not by name, to one "late eminent authority" who used to sneer at the regulation requiring the poor student to attend a hundred lectures in the session. He might have quoted others. Mr. GLADSTONE not long ago greatly astonished Mr. LYON PLAYFAIR by telling him that he never attended one academic lecture in his life. Medicine, either in its fundamental sciences or in its practical parts, is unfitted for much systematic statement apart from practical and palpable facts. It will be found that those lecturers command the largest audiences and the deepest attention who contrive to introduce into their lectures the greatest amount of facts and instances—in other words, who make their lectures more practical and less systematic. It is well to remember that science begins with the careful observation of facts, and ends with the systematic statement of what is observed; and this is the order and the way in which the student is most likely to be allured into studious habits and into a scientific frame of mind. Long systematic discourses are still more out of place now that the best books can be easily procured. Sir ROBERT'S illustrations, by which he would support the system of long lectures by the hundred, are, it seems to us, not more convincing than his arguments. He compares, or rather contrasts, the powers of the theatre, the pulpit, and the bar with the power of a book. But is it not true that the book is the growing power of the day, and that both the theatre and the pulpit are very much superseded by it? There is really not the difference between Professor CHRISTISON and ourselves which there may seem to be. He magnifies the power of lecturing. So do we when the lecturer is powerful. But what if he is prosy, and if the student is kept in dreary attendance, not by the instructiveness of the lecturer, but by the dry regulations of the University or the Medical Council? Most of his instances only confirm our main contention, that in medical teaching the systematic element must give place to the practical. Sir ROBERT CHRISTISON says Dr. HOPE, one of the most successful lecturers in the history of the Edinburgh University, gave no opportunity for practical study. But he tells the well-known secret of his great success when he informs us that Dr. HOPE'S course of 136 lectures was so complete and so fully illustrated "by never-failing experiments" that no diligent student ought to have found difficulty in taking up any branch of the subject practically. The case of Dr. JAMES GREGORY, the most captivating lecturer Sir ROBERT ever heard, proves too much. He was the apostle of bloodletting, which stood the test of half a century's experience. His mere eloquence gave a too long life to a bad practice. And who can doubt that if his descriptions of the virtues of bloodletting had been less systematic, more short and more clinical in character, more bound to square with cases and instances, medical practice would sooner have escaped from a false doctrine which has been at the root of much bad practice? We are not convinced, we repeat, that there is any necessity or advantage in students listening, or pretending to listen, to hundreds of dry systematic lectures. Lecturing may be the best mode of teaching; but the results of the present system are not flattering, and would justify a little more freedom both to teachers and students as to the way in which their work should be done.

* * *

UNLESS vigorous steps are taken to watch and compress the parliamentary results of sanitary legislation, we shall soon possess a mass of enactments to be rivaled only by those that relate to merchant shipping. The measure that it is now our duty to summarise—the Public Health Act—contains no less than 343 clauses, divisible into 10 so-called parts. It may be as well to remind our readers that nineteen measures are wholly and three partially repealed by this Act, which does not extend to Scotland or Ireland, nor, with some very few exceptions, to the metropolis; and so we propose to treat the measure as an original Act.

The second part of the Act is very important in that it describes the constitution, powers, and duties of urban and rural sanitary authorities, and is little more than a repetition of certain clauses of the Act of 1872. The third part, which really constitutes the backbone of the Act, embraces sanitary provisions as to sewerage and drainage, including clauses giving power to purchase, make, maintain, and cleanse sewers, and disallows the use of any natural stream or watercourse as an outfall until the sewage is freed from all excrementitious or hurtful matter. Drainage of undrained houses *must* be enforced by the local authority, and all persons are subject to penalties who build houses without drains, over sewers, or under streets, in urban districts. All the clauses relating to the disposal of sewage are permissive, and as such will require amendment at some future time, when the vexed question of sewage utilisation is practically settled. No house can be erected without a sufficient watercloset, earthcloset, or privy, and an ashpit properly covered. Orders on this score may be issued to the owners of factories, if special accommodation is required; and any urban authority *may* provide urinals, waterclosets, &c., for the public accommodation. Provisions for cleansing the streets and the removal of refuse are not made obligatory, except by order of the Local Government Board. The owner or occupier of any house that is in a filthy state may be made to whitewash, cleanse, and purify the same in accordance with the directions of the medical officer of health. Pigstyes, waste or stagnant water in a dwelling-house, and overflowing privies and cesspools, are classed as nuisances, and the owners subjected to a penalty. Foul ditches, collections of manure, or other filth, may be summarily condemned at the cost of the owners, and orders may be given for the periodical removal of manure from mews and other premises in urban districts. The clauses relating to water-supply, seventeen in number, are nearly all permissive in character; but the 64th clause vests all existing public cisterns, wells, &c., used for the gratuitous supply of water, in the local authority, who may close polluted wells and take measures to prevent the pollution of streams. Cellars may only be occupied under certain specified provisions; and common lodging-houses are subjected to rules which we need not here recapitulate, as they have undergone no material alteration. The question as to what constitutes a nuisance is so important that we quote the seven sections almost verbatim: (1) Any premises in such a state as to be injurious to health; (2) any pool, ditch, watercourse, privy, urinal, cesspool, drain, or ashpit so foul or in such a state as to be injurious to health; (3) any animal so kept as to be injurious to health; (4) any accumulation or deposit injurious to health; (5) any house so overcrowded as to be injurious to health; (6) any factory or workshop not kept in a cleanly state or insufficiently ventilated; (7) any fireplace or furnace not, as far as is practicable, consuming its own smoke. The 92nd clause makes an inspection of the district obligatory for the purpose of ascertaining what nuisances call for abatement; and notices may be served, and summary jurisdiction exercised, in respect of any nuisance. The 110th clause provides for the effectual work of Port Sanitary Authorities by classing all ships or vessels as houses, the master or other officer in charge being deemed to be the occupier; and a sub-section also includes in that provision school-ships and training-ships. Offensive trades are forbidden in urban districts without the consent of the local authority, who is empowered to make bye-laws with respect to them. The 115th clause also enables the authority of one district to take proceedings against any person creating a nuisance in an adjoining district—this section extending to the metropolis. Powers are granted to the medical officer of health or sanitary inspector to examine unsound meat or any other article intended for human food, and to apply to a magistrate for its destruction. The local authority is compelled, under the 120th clause, to see that houses are properly disinfected and cleansed, and that bedding or clothing which has been exposed to infection is disinfected or destroyed. It may provide a disinfecting apparatus, and maintain an ambulance for the removal of cases of infectious disease. Persons so suffering and without proper accommodation may be removed by order of a justice to a suitable hospital, as also persons found diseased on board ship. Persons labouring under contagious disease who expose themselves in the street, or travel in a public conveyance, are subject to penalties; and no one may expose or transmit infected clothing, or convey an infected person, without subsequently providing for the disinfection of the carriage, or let any room or house in which an infected person has lodged before such house has been disinfected, or make false replies to queries as to any such cases.

The Local Government Board reserves to itself the right, under the 130th section, of making any special regulations that may be deemed necessary with reference to cholera, both on land and water.

As regards hospitals, local authorities *may* provide them, and the patients (not being paupers) received into any such hospital are responsible for their own expenses during residence. Clauses relating to the prevalence of epidemic diseases enact that the Local Government Board may make regulations for the speedy interment of the dead; for house-to-house visitation; for the provision of medical aid and accommodation; the promotion of cleansing, ventilation, and disinfection; for guarding against the spread of disease; and for providing medical attendance. Mortuaries may be erected and maintained by the local authority.

We may omit all notice of Clauses 144 to 165 inclusive, which comprise provisions as to highways and streets, lighting streets, public pleasure-grounds, &c.; as also police regulations relative to public bathing, hackney carriages, &c. Parts 5, 6, and 7, relate to rating and borrowing powers, general provisions, and legal proceedings, which need not be particularised here. Part 8 relates to alteration of areas and union of districts; and Clause 286 provides for the appointment of a medical officer of health for two or more districts situated wholly or partially in the same county under the sanction of the Local Government Board, but no urban district containing a population of 25,000 and upwards can be included in such union. The Board may also assign to any parochial medical officer duties in way of rendering local assistance to the medical officer of health of any such union. The six following clauses are devoted to Port Sanitary Authorities, which may be temporarily or permanently constituted by order of the Local Government Board, who may entrust such authorities with any of the duties assigned to urban or rural authorities under the Act. Clause 291, which relates to the metropolis, constitutes permanently the City corporation the Sanitary Authority of the Port of London. Extensive powers are given to the Local Government Board as to directing and prosecuting inquiries relating to public health; and all inspectors of the Board are invested with powers similar to those of the inspectors under the Poor-law Acts. The miscellaneous provisions include compensation in certain cases to officers removed by the repeal of former sanitary Acts, and the making of bye-laws for the decent lodgment of hop-pickers. The saving clauses provide for the continuance of all sanitary authorities and officers as appointed under the Act of 1872, and for the protection of all outfalls or other works of the Metropolitan Board of Works. Special provisions are also made in the case of the local government district of Oxford.

We have endeavoured to give a brief summary of this very voluminous Act, as though it was an original enactment and not one of almost exclusive consolidation, omitting of course a great deal of matter with which medical officers have little or nothing to do. Critical comments upon the Act must be reserved for a future article. Meanwhile it is cheering to know that our sanitary laws are now at all events packed up in but one parcel.

The effect on the general system of suppression of the cutaneous secretion is a subject of very practical bearing. The process is supposed to be at the root of a large number of our common ailments, grave and trivial, and receives one of the highest places as a cause of disease on both the public and professional mind. A paper on the subject in the current number of Virchow's *Archiv* will therefore be perused with much interest. In it Dr. N. Sokoloff has described a series of careful experiments, the object of which was to determine the way in which the well-known effects are produced.

Two very different explanations have been given of the manner in which the application to the skin of a substance impermeable to water acts in leading, as it usually does, to the death of the animal. The old theory was that the arrest of secretion led to the retention in the blood and tissues of compounds which should have been excreted, and that these produced a poisonous effect. This explanation was accepted by Magendie, Gluge, Henle, Gerlach, and others. It has received a more definite form from the investigations of Edenhuizen, who believes that, in health, a small quantity of nitrogen is excreted in a gaseous form by the skin, or in indefinite chemical combination, as an ammonia, and not in a firm combination, as urea. If the excretion by the skin is hindered, the nitrogen appears as ammonia, or a similar compound, in the blood, and is in part deposited as triple phosphate in the subcutaneous cellular tissue and peritoneum. He believes that the retention of this compound in the blood is the source of all the morbid appearances observed during life and after death. On the other hand, Laschkewitsch concludes from his researches that the effects on animals are due solely to the increased loss of animal heat which the experiments entail. He found that by wrapping a varnished animal in cotton-wool its life, and even health, may be preserved. The effect of the artificial suppression of perspiration is dilatation of the cutaneous capillaries, the vaso-motor nerves being paralysed by the application to the skin. The result of the vascular dilatation is rapid loss of heat to such an extent as to be incompatible with life.

It was to ascertain to which of these causes, if to either, the results are to be ascribed which uniformly follow the arrest of the secretion of the skin that Dr. Sokoloff's experiments have been undertaken. They were made upon dogs and rabbits. A varying extent of the skin was bared and covered with a substance capable of preventing the transudation of moisture. Various varnishes were employed, but it was found that the most satisfactory application was a thick oil. A comparison of a considerable number of experiments showed that the effect on the internal temperature varied according to the area of the skin on which the application was made. If the application was a very partial one, during the first days there was either a slight elevation of temperature (in the dog), or a slight fall (in the rabbit); but the deviation from the normal was never considerable. Subsequently there was a slight rise, followed by a fall; and simultaneously a series of symptoms indicated the commencement of serious organic mischief—general weakness, loss of appetite, evidence of weakened heart, dyspnœa, &c.; and these symptoms continued till death. In a few cases death was sudden and unexpected. If the whole, or nearly the whole, skin was painted, a quick and considerable fall in temperature occurred, and the manifestations of general disorder were much more rapid and stormy, and appeared often simultaneously. If the theory of Laschkewitsch were correct, the observations should show a proportion between the loss of heat and the resulting symptoms; but this was far from being the case. Where the application was partial, there was at first no invariable fall; in some cases there was actual pyrexia; it was only at the last that a considerable fall occurred. Admitting the coincidence of lowered temperature and the gravest symptoms, the causal relationship between the two is, in Dr. Sokoloff's opinion, far from being proved. If varnishing an animal causes vaso-motor paralysis of its cutaneous vessels, the effects on the temperature should resemble those in paralysis of the sympathetic, or after section of the spinal cord. In the latter case the temperature, normally considerably higher in the rectum than on the skin, falls, and falls everywhere in a uniform degree. In the case of arrested perspiration, however, the internal temperature was uniformly warmer than the external, both on the day after the application and until death. May not the loss of heat be due to increased conductivity of the varnished or oiled skin? This is probable, for the mere removal of the hair is sufficient to reduce the animal's temperature; and some experiments showed that it might, indeed, be a sufficient cause to account for the total fall in the experiments. It was found that cotton-wool did not maintain the temperature, as was assumed by Laschkewitsch; and Valentin found that an artificial supply of heat, although it rendered the animals more lively, did not prevent or postpone for long the fatal result.

On what grounds does the theory of a blood-poisoning rest? The main symptoms are albumen in the urine, weakened cardiac and respiratory action, and certain nervous troubles. After death, an inflammation of the parenchymatous organs is always found, those which suffered the most severely being the heart, liver, kidneys, alimentary canal and muscles, with signs of general œdema. The analogy with the effects of some poisons is certainly very close; and the hypothesis affords a better explanation of the phenomena than any other. The relation between the symptoms and the organs affected, in the case of the kidneys, is very intimate. It is impossible to overlook the obvious significance of the general œdema of organs and tissues, and of the presence of albumen and formed elements in the urine. The albuminuria, indeed, appears early, and increases as the symptoms increase. This is, then, to be regarded as one of the gravest consequences of the suppression of the perspiration—a result which agrees well with every-day clinical observation. It is probable, indeed, as clinical observation would also suggest, that many of the later troubles from which the animals suffer are secondary to the renal mischief. Of this, however, no direct evidence was to be obtained.

Microscopical examination showed nothing abnormal in the blood of animals suffering from the more intense consequences of the application. A more severe test was applied to it by injecting a portion of blood taken from an animal in the act of dying into the blood of a healthy animal. The results of several such experiments indicated a slight poisoned quality in the injected blood. Albumen quickly appeared in the urine, soon lessening, and disappearing on the fourth or fifth day. No albuminuria followed the injection of healthy blood or of distilled water. Thus the consequences of the injection are not the same as those of the suppression of the perspiration. In the one case the symptoms are slight and transient; in the other, grave and persistent. But in each case the kidney appears to suffer the most severely. No depression of temperature follows the injection of the morbid blood—a fact relied on by Laschkewitsch as evidence that no blood-poison is present. In the opinion of Sokoloff, however, the fall in temperature is less uniform, less related to the constitutional symptoms, than is the evidence of kidney affection, and he thus concludes that the blood of the animals experimented on contains a substance capable of exciting the same symptoms, though in less intensity, in a healthy animal. It must not be forgotten, however, in estimating the value of this opinion, that the symptom relied upon is one common to a large number of blood-poisons, and as such is of perhaps less value than any other as indicating identity of action, much less unity of nature. The poison of scarlatina, of diphtheria, of a dissecting wound, may all cause the appearance of albumen in the urine in the same form as a violent chill to the surface; but no more inference can be drawn as to their common character than from the presence of pyrexia. However suppressed action of the skin acts in causing parenchymatous inflammation of organs, that inflammation once set up must lead to a state of blood quite capable of causing, if injected into a healthy animal, slight symptoms of blood-poisoning, and, among the rest, albumen in the urine, without there being any necessary identity in the initial process in the two cases. M. Sokoloff's experiments are of considerable interest and importance, and his conclusion may be correct; but we cannot think that it is adequately proven by the facts he adduces in its support.

Much, we had almost said everything, is left by the Artisans' Dwellings Act to medical officers of health. New duties are imposed upon them, a large responsibility rests with them, and it cannot be disguised that they must henceforth enjoy the most extended opportunities of urgent and useful work. That they will encounter serious opposition, and have to face difficulties and dangers hitherto unknown, in the discharge of their proper functions, is inevitable. The task entrusted to their care, and the confidence reposed in their public spirit and sagacity, will call for tact, wisdom, and, we fear, in not a few cases, self-sacrifice. It will conduce sensibly to success if, without delay, measures are taken to obtain a clear view and mastery of the new duties. The preamble of the Act (38 & 39 Vict., c. 36) states the need for legislation, and points to the objects which should be ever present to the medical officer, with significant perspicuity.

> "Whereas various portions of many cities and boroughs are so built, and the buildings thereon are so densely inhabited, as to be highly injurious to the moral and physical welfare of the inhabitants; and whereas there are in such portions of cities and boroughs as aforesaid a great number of houses, courts, and alleys, which, by reason of the want of light, air, ventilation, or of proper conveniences, or from other causes, are unfit for human habitation, and fevers and diseases are constantly generated there, causing death or loss of health, not only in the courts and alleys, but also in other parts of such cities or boroughs," &c.

The area of reform, it will be seen, comprises not only the removal of constructional nuisances, but the elimination of all "other causes" "injurious to the moral and physical welfare of the inhabitants" of a district, and which make it a source of danger to "*other parts* of such cities and boroughs." It is important to bear this last point clearly in mind. The business of applying the remedy provided by the Act rests with the "Local Authority," subject to the supreme jurisdiction of the "Confirming Authority"; but the medical officer of health is himself the authority which must set the work of reform in motion. He is to make an "official representation" to the Local Authority "whenever he sees cause to make the same" (Sect. 4). It will, therefore, be the duty of medical officers to search out and expose the sanitary conditions which lie at the root of epidemic and prevalent disease and impair the "moral and physical welfare" of the people. How much zeal and knowledge of sanitary affairs are indispensable for the efficient discharge of this onerous first duty it is not necessary to explain. Looking to the absolute requirements of the case, it is startling to find the Legislature has left the authorities to reward their officers "with what remuneration they think fit." After the medical officer has made his official representation, the Local Authority may pass "a resolution in favour of an improvement scheme," or they may fail to do this. In any case, a copy of the report of the medical officer is to be sent to the "Confirming Authority"—i. e., Her Majesty's Secretary of State for Home Affairs, for the metropolis, and the Local Government Board, elsewhere. The medical officer's report or representation is to state "the facts," and declare "whether, in his opinion, the area is an unhealthy area or not an unhealthy area for the purposes of this Act." These "purposes" are, as we have shown, set out broadly in the preamble; and by the evils and defects there indicated the medical opinion must be determined. Occasionally, no doubt, the Local Authority will neglect or decline to recommend a costly reconstruction, and the medical officer will then, practically, stand charged with the duties of a public prosecutor in the cause of moral and physical health. In this position he will be required to support his allegations "by such evidence as the Secretary of State or Local Government Board may from time to time require." It will save a world of trouble, and avoid the risk of failure and discredit, if medical officers at the outset take ample measures to complete the case on which their "representation" is based, and to collect the evidence by which it is to be supported. If a medical officer fails, or is supposed to fail, in his duty, two or more justices, or twelve ratepayers acting together, may "complain to him," and require his report on a particular area. If his report is questioned or disputed, or, indeed, in any case, an inquiry will be ordered by the Confirming Authority, and an officer, representing the latter, will be sent to the district to verify the correctness of the official representation made to the Local Authority, and to inquire into the sufficiency of the scheme provided for improving the area, and into any local objection to be made to such scheme. It does not appear that the medical officer is required to suggest a scheme of his own to the Local Authority. His representation is, by Section 3, defined to be a declaration "that any houses, courts, or alleys within a certain area under the jurisdiction of the Local Authority are unfit for human habitation, or that diseases indicating a generally low condition of health amongst the population have been from time to time prevalent in a certain area within the jurisdiction of the Local Authority, and that such prevalence may reasonably be attributed to the closeness, narrowness, and bad arrangement, or the bad condition of the streets and houses or groups of houses within such area, or to the want of light, air, ventilation, or proper conveniences, or to any other sanitary defect, or to one or more of such causes, and that the evils connected with such houses, courts, or alleys, and the sanitary defects in such area cannot be effectually remedied otherwise than by an improvement scheme for the rearrangement and reconstruction of the streets and houses within such area, or of some of such streets or houses." He is not required to say in what the rearrangement or reconstruction ought to consist, but he *is* required to discriminate between remediable and irremediable causes of unhealthiness, and in the process of making this clear the scheme will practically be evolved. We are not prepared, however, to recommend medical officers to wander beyond the limits of their duty, and it is probable that much personal difficulty and peril of unpleasantness will be spared if they are careful to avoid the espousal of particular plans in which special interests may be concerned or affected. The civil medical officer of health is not in the position of the military medical officer, who may be called upon to mark out the area of a new camp. He has simply, boldly, and scientifically to deal with the state of things which exists, with the immediate sanitary condition of the area and its remote consequences, and he will do wisely to confine his professional services within these bounds. The opinion of a medical officer as to what new works may be expedient or necessary should be pronounced *after* some scheme has been submitted to him by the Local or the Confirming Authority, not before. This is the more necessary, because, as regards the question of sanitary fitness and sufficiency, he will be called upon to act as adviser, and perhaps as witness. His opinion should, under no circumstances, be expressed upon a scheme unofficially laid before him, and to which he might unwittingly be made party.

Annotations.

"Ne quid nimis."

DISEASED CATTLE.

WE trust the Privy Council will not be induced to relax any regulation necessary to protect the public from the sale of diseased, or even possibly diseased, meat. There appears to be a combination of the importers of foreign cattle to force changes upon the Government which may be fraught with danger to the community. As a general principle, it must be maintained that an efficient quarantine is indispensable in the case of cattle coming from countries or ports recently infected, or known as the frequent centres of disease. It is also clear there can be no safety in allowing a herd, some members of which have exhibited symptoms of a malady, to enter the market without conclusive proof that it is not further contaminated. Whether it may be necessary at once to slaughter the whole cargo, or if it is even wise to resort to that summary measure, are questions which may fairly be discussed. Possibly a crucial test might be applied to the *bona fides* of an importer by allowing him to keep, if he will, the remainder of a herd, after the destruction of any affected animal, until such time as the proof of its health may be complete. If an importer were prepared, and preferred, to maintain his cattle in quarantine, under rigorous inspection, at his own cost, instead of having them slaughtered, it would go far to show that proper care had been exercised in their selection at the port of shipment, and to ensure the utmost precaution as to further imports. The public are primarily interested to secure healthy stock and fair prices. It is easy to understand that importers do not care to face the loss of value on a whole herd whenever a single animal may be affected. To reconcile the interests of the dealer with those of the consumer it may be necessary to make some sacrifice, but the concession must not involve any weakening of the barriers by which we keep out disease. Our home breeders and graziers have already lost so heavily by the importation of diseased cattle that, at all costs, they must be protected. If an importer is sure that the great body of his herd is not infected, he will probably find it to his advantage to keep it for a sufficient period, after the elimination of any individual case of disease, to convince the authorities that it is perfectly healthy. If he entertains a doubt on the subject commercial prudence will prompt him to submit to the inevitable loss consequent on immediate slaughter. Beyond this concession, with safe conditions, the Privy Council should not be persuaded to go. It is no argument against maintaining proper restrictions upon the importation of cattle and sheep that our own herds and flocks are unfortunately affected. If we hope to stamp out the disease we must not only isolate infected districts within these islands, but rigorously protect the whole United Kingdom from the new poison threatening us from without. The circumstance of our being already infected increases the urgency of this last precaution, instead of diminishing it, as popular writers suppose and insist. Nor is it unreasonable to impose more stringent regulations on cattle imported from abroad, even from our own colonies, than on those brought from places within the United Kingdom, such as Ireland and Scotland. The condition of districts under our own immediate inspection is better known, and they can be more readily subjected to special restrictions than those over which we have no control and for which we are not directly responsible. It is much to be regretted that the obvious fallacies involved in these specious contentions should be overlooked by the press, albeit we may hope the authorities will not be misled or mischievously influenced by the idle sophistries urged in the interests of a particular mercantile venture and in strange indifference to the public health.

DISTRICT NURSING.

IN continuation of the Special Report on the National Nursing Association that appeared on the 14th inst., we have to notice an important Appendix, compiled by Miss Nightingale, on district nursing. The training for this work must be of a kind that does not and cannot exist in a hospital, and district training is essential after the year's hospital training. If this be not accomplished, and in a systematic way, the nurse does not really nurse, but degenerates into a giver. She very rarely sees, or receives directions from, the medical attendant, but on her own responsibility applies lotions and dressings, or administers beef-tea, &c. "She goes her own way." The district nurse should be taught, among other things, to do without the appliances found ready to hand in a hospital; but inasmuch as there is nothing, so to speak, to keep the district nurse up to the work, she requires "retempering" in the hospital at least three months every two years. It is proposed in connexion with the work of the National Association, that the district staff should be supervised by a lady superintendent, having head-quarters in the training school, which latter should be contiguous to the hospital. Where small district homes are established the superintendent should reside occasionally at each of these institutions, but the nurses should be selected, appointed, dismissed, and paid by the hospital superintendent or matron, to whom also the district superintendent should be responsible. In order to avoid the inevitable tendency to become "givers" rather than nurses, it is proposed to institute a system of checks or tickets, or what the French call "bons," which may be given when nourishment, bedding, &c., are seen to be urgently required, which may be presented and exchanged at the district home in the immediate neighbourhood. Miss Nightingale, in conclusion, says:—"On the whole, it would seem to require a higher class of woman to be a district nurse than even to be a hospital nurse. If the district nurse is merely an ordinary sort of woman, she does not find enough to do, except in epidemic times, when she is overwhelmed. There is not enough to do in healthy times to occupy an inferior class of woman; but how much too much to do in teaching the poor cleanliness, care of children, how to obtain fresh air, how to prevent disease, &c." The forms and rules used in the District Nursing Association at Liverpool are very favourably reviewed. It cannot be too emphatically insisted upon that the governing bodies of these associations, whether in metropolitan or urban districts, should learn accurately the extent of powers relating to health granted by the Acts to the various local boards. Medical officers of health, parochial surgeons, and sanitary inspectors may aid and be aided also in the performance of their own duties very materially by an interchange of information with the members of a staff such as this Association is endeavouring to supply.

CERTIFICATION BY UNQUALIFIED PERSONS.

AT Hammersmith, according to the report of *The Times*, Mr. William Camley Smith, of Allen-terrace, Kensington, was summoned, at the instance of the Kensington Board of Guardians, for falsely pretending to be a registered medical practitioner by signing a medical certificate under the Vaccination Act, to the effect that a certain child was not in a fit state to be successfully vaccinated. Mr. Draper, clerk to the board, attended in support of the summons; Mr. Claydon defended. Two certificates were produced. One purported to be signed by Percy Leslie, M.D., 1. Allen-terrace, Kensington, and the other bore the signature, W. C. Smith, *pro* Percy Leslie, M.D., both in the same handwriting, and relating to two children of different parents. Mr. C. Shattock, the officer appointed under the Vaccination Act, said that there was a brass plate bearing the defendant's name on the gate where he resided. At one time Dr. Leslie's name was on the gate, but it had been down for months. Since the proceedings had been taken another plate had been put up. Dr. Leslie resided in Westminster. Dr. Percy Leslie said he was duly registered. It was a common practice for unqualified practitioners to be employed in hospitals and by general practitioners. He had known the defendant for four years. He studied and lived with him in Westminster. The defendant removed to Kensington, and for a year he had ceased to be his assistant. Since the defendant had been in Kensington witness had been there very often. No doubt the defendant was constantly in the habit of signing certificates for him. There was no other alternative, as he could not always be at home. The witness further stated that he did not see the child Green on the day mentioned. The father was not his patient. Mr. Bridge said it was absurd to say that the defendant was Dr. Leslie's assistant. He came down to Kensington, put up a brass plate, and acted as a doctor. It was not a case of an assistant signing a certificate for his master. He fined the defendant £10, and ordered him to pay two guineas costs additional, with the alternative of two months' imprisonment.

It is to be hoped that the above case will serve as a warning both to unqualified persons and to practitioners who co-operate with and countenance them. It would take a lawyer to say what were the varying degrees of relationship between Mr. Smith and Dr. Percy Leslie at different times. A letter elsewhere throws a little light on the subject. At one time they were so intimate that Dr. Leslie's name was on the defendant's brass plate. This had been discontinued, but from the evidence it would seem that there survived such a friendly understanding between him and Dr. Leslie, that the defendant was "constantly in the habit of signing certificates for Dr. Leslie." We agree with Mr. Bridge, that it is absurd to regard the defendant as Dr. Leslie's assistant. The distance, the perfectly distinct houses, the fact that the patients whose vaccination was formally certified by the use of Dr. Leslie's name had not been seen by Dr. Leslie, and the removal of his name from the brass plate, all make this theory untenable. We have always maintained that to put an unqualified assistant in a separate house, and at a distance, is an unjustifiable use of an unqualified assistant. To give him the use of one's name, even for the inevitable difficulty of certification, is not only unjustifiable but illegal. It is an attempt to put a man into practice without the qualifications required by the law, for which other men have to labour hard and pay much. It is unjust both to the public, who are misled, and to the profession, which has always little enough protection at the hands of the law. The case of Mr. William Camley Smith shows that such a system is not only illegal but costly, and we may hope for its entire discontinuance.

THE DUTY OF TAKING HOLIDAY.

The medical profession is a hardworking one. We "spurn delights and live laborious days" to a greater extent probably than any other men. And what is worst of all, we have often to follow up laborious days with equally laborious nights. Large portions of our time have often to be spent in attendance on patients who live in close rooms and in all sorts of unhealthy conditions. Yet, notwithstanding—perhaps partly in consequence of—all these peculiarities in our lot, we have, of all men probably, the least adequate idea of the necessity of a break in the monotony of our accustomed toil. We lately met a respected and still active member of our profession who said he had not spent two nights out of the town in which he practises for forty years excepting the time when he had the typhoid fever. Fancy forty years of country practice with no memory of a holiday but what is involved in having typhoid fever! There is much in such devotion to work to be greatly admired, and that is worthy of study in a time when younger men seem to think that half their life is to be given up to pleasure, or, as it is called, recreation—so much that we can scarcely find it in our hearts to blame it or to say that it should have been otherwise. Yet we think that life was not meant to be so full of labour as this. Doubtless it is possible to some men even at home and in harness to get such changes of occupation as give the sense of rest. But to most men holiday is only possible away from home and out of harness. Their tendency to work is so strong that they will work unless entirely removed from the sphere of work. Besides, the essence of a holiday, especially of a medical man's holiday, is irresponsibility—the feeling that nobody's life or health is depending on his action. It matters comparatively little where we go or what we do, so that we get somewhere—anywhere—out of the world of surrounding work into some solitude or some society where our calling will not be suspected and we shall be treated as useless functionless people. The medical man's holiday has this advantage, too, that it takes him away from the region of sickness and its associations. Though our familiarity with disease and the frequency with which it succumbs to our "lenient arts" make us to be less painfully affected by it than otherwise, there is still something grave and depressing in our work from which it is well to escape for a time. On all these grounds we urge our readers to remember, amongst other duties, the duty of taking a holiday. The winter was long and arduous; serious disease was prolonged far into the summer, and allowed medical men but scanty leisure. We should act on the advice we are so fond of giving—take a holiday. No doubt there are little difficulties in the way, but they can be overcome. Let us trust a little more to the magnanimity of our patients and the friendly kindness of our professional brethren. Let us also do all we can to smooth the way for our neighbour's holiday and to make it pleasant, so that winter may find us all with renewed powers, with fresh interest in our work, and with pleasant reminiscences of our own holiday and that of our brethren. Equal to the pleasure of getting a holiday is that of helping some hard-worked neighbour to get one.

CHEMISTS' PRESCRIBING.

We think the public should feel grateful to Dr. Diplock for lately directing attention to the evils of chemists' prescribing, and for enforcing his remarks by several illustrations of the absurd mistakes made by chemists who thus misunderstand their duties. He had known a mustard plaster ordered to the chest for the good of a fractured skull, and chalk-mixture prescribed for effusion on the brain. It is becoming quite common for chemists to go on prescribing for cases until they become serious, or until evidences of impecuniosity on the part of the patient appear. Perhaps the best remedy for this is the publicity of cases of the kind which called forth Dr. Diplock's remarks. In this case the little child was under the care of a local chemist, a medical man being called in only to find the patient dying of inflammation of the lungs. It is clearly right in such circumstances to withhold certificates. The action of the chemist should be investigated and exposed, and it can only be so satisfactorily by a jury. It is fair to assume that life might have been saved by early application to medical men; and for preventing this and possibly maltreating the case, the facts should be fully brought to light. There is the more reasonableness in medical men refusing to shield chemists who act the part of doctors, that medical advice and even medicines are now within the easy reach of all classes.

FALLACIES OF FIGURES.

We are each year becoming more statistical, and at the close of the Parliamentary session thoughtful people are especially prone to practise the virtue of faith in figures. There is no virtue which more easily runs into a vice. The false estimates formed of local healthfulness from mere numerical returns of local health, or of the public progress in morals and sobriety from the report of "drunk and disorderly persons arrested by the police," are gross instances of the folly of trusting wholly to figures. It needs no very acute reasoning to discover that if any locality enjoys so high a reputation for salubrity that numbers of sick people flock to it, diseases prevalent in the neighbourhood are likely to be numerous, and the death-rate will probably be large. In the same way the circumstance that only 26,155 "drunk and disorderly" cases have come under the official notice of police inspectors during the past year, as against 29,755 in the year before last, may be as easily accounted for by the possibility that the police fail, from some cause, to arrest so many persons falling under this technical description, as on the presumption that there are not so many cases of the kind to be arrested. There are, however, other and less apparent sources of fallacy to which the attention of social philosophers may be usefully directed. For example, although only 120 bakers have been proceeded against within the last year for commission of the "smoke nuisance," that may proceed from compliance with the wishes of inspectors in the matter of adopting specially recommended apparatus quite as much as from increased compliance with the law. We do not say this hypothetical explanation is the true one, but there clearly ought to be no room for question. It is of the last importance just now to see that all inspectorial work is discharged vigorously and impartially, with a single eye to the public advantage. If Acts conducing to the general health, comfort, and convenience are to be worked efficiently, they must be carried out in their integrity by an agency which is official and nothing more. It will sensibly help to bring about the reforms we so much desire if the reports of our administrative authorities are closely and carefully studied, but it is not enough to take the figures as they stand. Every possible error and misconception must be eliminated from the judgment deduced, and this requires a rigorous search for the fallacies with which almost every return of the kind abounds, and which being disregarded will too certainly mar its value.

THE CLINICAL THERMOSCOPE.

AN ingenious instrument for detecting variations in the temperature of the surface of the body has been invented by Dr. Edward Seguin, of New York. It is, as he describes it, "intended as a quicker and more delicate test of differential temperatures than the thermometer, and less to give the degrees of heat than the velocity of its radiation." It consists in a glass tube seven inches in length, and with a bore of one quarter of a line, closed at one end by a bulb nine lines in diameter, and open at the other end by slight enlargement of the tube. To prepare it for use the air in the instrument is rarefied by immersion of the bulb in hot water, and, this being effected, the open mouth of the tube is plunged an inch deep into cold water, and then quickly withdrawn. A "water-index" is thus formed, the only difficulty being that the air may not have been sufficiently heated or else overheated, so that the index either does not reach the bulb or else falls into it. A sliding scale of inches or centimetres is applied to the tube, so that its lowest figure corresponds to the level of the head of the index. Dr. Seguin claims for this little and simple instrument considerable value in detecting the amount of radiation from the surface of the body, and gives two instances in which he had found it of service, in the one in detecting local inflammation in the hypogastric region in a case at first mistaken for typhoid, and in the other in diagnosing fracture of the base of the skull. In the latter case the temperature in the axilla was 98·5° F., and the index of the thermoscope rising in the hand, axilla, and elsewhere, fell rapidly in the inner angle of the orbit. He also speaks of his thermoscope as being the best means to be employed for the proof of death, as evidenced by the index remaining stationary when applied to the body. Dr. Seguin calls the clinical thermoscope "an instrument of diagnosis in physic and surgery, a monitor in the nursery, a test in the physiological laboratory, also a necrometer in the dead chamber."

POOR-LAW MEDICAL RELIEF IN SCOTLAND.

DR. JOSEPH ROGERS, Ex-President of the Poor-law Medical Officers' Association of England, read a most important paper at the recent meeting in Edinburgh "On the Anomalies and Deficiencies of Poor-law Medical Relief in Scotland." He shows the absurd want of appreciation of medical service for the poor which obtains in that religious portion of the kingdom, and the inequality in the provision for such services in different parishes. Take New Deer and Old Deer in Aberdeenshire. New Deer had a population in 1871 of 4853, of which number 152 were registered poor and their dependants, 50 were casual poor and their dependants, and 7 lunatics. Medical relief cost £30, medicines being found by the medical officer. The total gross relief amounted to £803 9*s.* 2*d.* Of this number of paupers 7 died or were otherwise got rid of in the course of the year. Old Deer had a population in 1871 of 5085; there were 257 registered poor and dependants, 94 casual poor and dependants, and 24 lunatics. Of this number 30 died or otherwise disappeared. The total poor relief was £1624. Although the population, pauperism, gross relief, sickness, and mortality were so much greater than in New Deer, the stipend out of which everything had to be found was only £9 10*s.* 1*d.* more than in New Deer. A striking instance of the disparity between Scotland and Ireland, as regards the provision of medical relief, is shown by comparing the case of Aberdeen, with a population of 47,077, and the medical relief costing £246 6*s.* 10*d.*, and that of Dungannon, with a population of 45,990, and medical relief costing £1069. In Aberdeen the whole cost for poor relief is nearly three times what it is in Dungannon—that is, £12,512 16*s.*, instead of £4587. In the parish of Bourtie they give the medical gentleman a guinea a year as a retaining fee, and for every pauper he attends just according to what he may charge, or what may be considered a reasonable compensation. The population is 499. In 1869, the total cost of medical relief was £1 11*s.* 10*d.*; the total of paupers and dependants was 25, of whom 2 died. Fancy a medical man being required to attend 25 paupers for a year, 2 of them in fatal illnesses, for £1 11*s.* 10*d.*, including, we presume, the retaining fee. No wonder that Dr. Rogers finds ample illustration of his proposition, that inadequate medical relief always coincides with excessive pauperism and an excessive death-rate. Dr. Rogers has partially exposed a most unsatisfactory and discreditable system—bad for the poor and for the ratepayers, and very bad for medical men. It will be the fault of the Poor-law medical officers in Scotland if the exposure is not completed, and a remedy provided.

UNQUALIFIED ASSISTANCE.

AN inquest was held the other day in the neighbourhood of Durham, on the body of an agricultural labourer who died suddenly in the course of an acute illness, apparently rheumatic fever, he having been attended only by the unqualified son of an unqualified practitioner in the neighbourhood. Vomiting preceded death, but there was nothing, in the opinion of a surgeon who saw him just after he died, which might not be accounted for by the cardiac failure not uncommon in cases of acute rheumatism. An inquest was rightly called for, and a verdict was returned, founded on the opinion of the surgeon who listened to the evidence, that the deceased died from inflammation of the covering of the heart. It is a case, however, in which there certainly should have been a post-mortem examination. None was made, apparently because it would have been necessary to do it by candle-light, and the opinion was expressed by the surgeon to whom the examination was entrusted, that "it was not advisable to make a post-mortem by candle-light." An examination by candle-light is much better than no examination at all. When pericarditis, the supposed cause of death, is sufficiently intense to lead to a fatal issue, its pathological appearances are usually obvious enough. The extent to which the poor are still under the care of unqualified practitioners is much to be regretted. No doubt there are some good and well-informed practitioners who possess no qualifications, but the sick have no guarantee against the grossest ignorance, and often no choice but to commit themselves to the care of absolute incompetence. In this instance the "medical student" in charge of the case appears, from the report of the inquest, to have had no conception of the fact that the gravest complications may arise and lead to sudden death in the mildest case of rheumatic fever, and apparently judged of the state of the heart only by feeling the pulse.

DRUGGISTS AND THE NORWOOD POISONING CASE.

IT would be premature to comment on the remarkable facts which constitute what is known in the papers as the Norwood poisoning case. One incident in the case, however, may be noted without prejudice to the prisoner, as it illustrates an evil to which we have referred elsewhere, and which has lately been commented on by a metropolitan coroner. We refer to the prescribing practices of druggists, and the way in which they administer over their counters the strongest medicines. It is true that both the chemists examined on Tuesday as having been asked by the prisoner for strychnine were able to say that they had refused it. So far so good. But one of them, Mr. Windle, of Thomas-terrace, Lower Norwood, seemed to admit in his evidence that he had supplied the prisoner with two draughts containing nux vomica. We protest against such practices on the part of druggists. Notwithstanding the law against the sale of poisons, it is evidently possible for a person to go about from one chemist to another to get doses, perhaps fatal ones when multiplied, of deadly drugs. There is no excuse for such conduct, and the sooner it is made illegal, if it is not so already, the better in the interest of the public.

A NOVEL (!) VIEW OF TYPHOID FEVER.

WE have received a pamphlet by Dr. Morton, of Sydney, which purports to contain certain novel views as to the etiology of typhoid fever. The pamphlet is a peculiar one. It has the merit of brevity, and in great part consists of extracts from the writings of standard authors on the continued fevers, by which the pamphleteer endeavours to show that all the forms of fever, "febricula," "relapsing," "typhoid," and "typhus," are identical. Thus does he calmly assume that the labours of Jenner and Stewart are of no value. By no means a novel view this, but rather a reversion to the old days of incomplete clinical and pathological observation. The reason assigned by Dr. Morton for identity is that in all these diseases there is found after death fluidity of blood and congestion of internal organs. The rest of the pamphlet contains a statement of the writer's belief that typhoid fever is due to the absorption of gases from the alimentary canal of the patient, and on this he bases his treatment, upon which we need not dwell. In fact, we have already dwelt longer than necessary on this last contribution from the colonies. Happily all our brethren at the antipodes do not embrace the "novel" views of Dr. Morton.

HYDATID CYST OF THE LIVER.

THESE cases are very frequently seen in hospital practice, and generally yield to treatment, especially when tapping is had recourse to. In most instances such tapping is innocuous, but it should be remembered that sudden death may occur after this operation. This misfortune lately happened to M. Martineau, at the Lariboisière Hospital of Paris. The patient was thirty-one years of age, and presented at the epigastrium an indolent, dull-sounding tumour, with all the symptoms of a hydatid cyst. Tapping was resorted to with a capillary trocar. Very little clear fluid was obtained, and on removing the trocar it was found obstructed by a shred of membrane. The patient in the meantime turned pale and faint; he vomited some wine, and threw up much white mucus from the bronchi. In twenty minutes, in spite of the most active means, he breathed his last. Two cysts, the size of fists, were found on the under surface of the liver, one under the right, the other under the left lobe. No peritonitis. M. Martineau considers that the fatal issue was owing to reflex paralysis of the pneumogastric.

A fact worthy of note is the assertion of M. Guyot, made at the meeting of the Medical Society of the Hospitals of Paris, where this case was read, that he had been acquainted with seven or eight cases of death within twenty-four hours after tapping of the liver. Although many cases have been mentioned where, not hydatid cysts, but the liver itself was punctured without evil consequences, we should bear in mind the possibility of untoward results in this operation.

THE CORONER FOR CENTRAL MIDDLESEX.

DR. HARDWICKE is attempting to perform the difficult feat of serving two masters. He was elected a few months ago triumphantly, if not in spite of the Middlesex magistrates, at any rate in support of the principle that inquests should be made real by an actual ascertainment of the cause of death in doubtful or suspicious cases. During his candidature he intimated his intention to follow in the steps of his predecessor and of Mr. Wakley, who by judicious use of the power of ordering post-mortem examinations to be made, elucidated whole classes of otherwise mysterious deaths, and thus exposed sometimes carelessness and sometimes crime. No sooner was Dr. Hardwicke duly and most victoriously elected to continue the work of such predecessors, than he intimated his determination to consult, much more than his predecessors, the views of the Middlesex magistrates. And now he has his reward. Captain Morley is quite eloquent and happy over the reduction in Dr. Hardwicke's accounts — "less by £112 10*s.* 6*d.* than Dr. Lankester's, and the post-mortem examinations less by forty-two." All we shall say is, that the reputation attaching throughout the country to the coronership of Middlesex is associated with a regard, not to pounds, shillings, and pence, but to the value of human life and of any investigations which may show how it is lost or wasted.

THE HEALTH CLASS OF THE MIDLAND INSTITUTE.

THE Council of the Midland Institute has again invited Dr. Richardson to deliver the inaugural lecture. The invitation has been accepted, and the lecture, which will be delivered on Monday, September 13th, at 8 P.M., in the Masonic Hall, Birmingham, will be on the subject of "Tobacco in relation to Health." Last year the "introductory" was on Alcohol, and many thousands of the published abstract of it were sold.

The course will, as heretofore, be continued by Professor Corfield, whose labours in previous sessions have been eminently rewarded in the results obtained by his pupils. The name of the usefully liberal founder of these Health classes remains still unknown.

HOSPITAL MORTALITY.

THE Statistical Society has chosen, as the topic of its prize essay next year, the subject of hospital mortality. The question is undoubtedly one of the highest importance, and a careful and unbiased analysis of the facts and statistics at present available upon the subject cannot fail to be instructive. We are not very sanguine, however, that the question can be settled by statistics. One term of the comparison on which all depends may be ascertained with something like accuracy and completeness; the history of the grave occasional epidemics of disease with which hospitals are visited, and which no one disputes, may be detailed with effect; but the other term, the statistics of private practice, cannot be ascertained on a scale sufficiently extensive and reliable to make a statistical comparison of much value.

A NEW PROCESS OF STAINING TISSUES.

THE well-known histologist, M. Cornil, has recently introduced "violet of methylaniline" as a reagent for staining tissues in microscopical research. Its merit lies in the separation of its constituents into red and blue, each of which has affinities for different parts of the tissue. This is especially well seen when applied to organs in a state of lardaceous degeneration, the lardaceous parts taking a red tint, the normal a blue. By this method M. Cornil has ascertained that the first seat of the lardaceous process is in the interior of the small arteries, the endothelium of which, as well as the outer and middle coats, remaining intact for a considerable time. The objection to the process, which will certainly militate against its general adoption, lies in the fact that the colouration disappears in preparations mounted in the ordinary media, as glycerine, Canada balsam, &c.

THE SWIM ACROSS THE CHANNEL.

CAPTAIN WEBB has accomplished the great task which he had set himself without any rhodomontade or flourish of trumpets. The qualities requisite for such an unprecedented feat distinguish Webb as a phenomenally powerful man. The courage, endurance, and physical strength displayed will henceforth, no doubt, serve as an illustration of the amount of strain the human frame is capable of sustaining. It was to be expected that he would have shown some signs of exhaustion at the finish, but it does not appear that he is any the worse for his perilous trip. We understand that it is contemplated to present Webb with a practical expression of that admiration which plucky deeds never fail to arouse among Englishmen. If, as we are informed, he is the son of a medical man, the profession might well assist in rewarding the brave fellow.

THE PHARMACEUTICAL CONFERENCE.

THE Pharmaceutical Association of Great Britain held their twelfth annual conference at Bristol this week. Proceedings were commenced on Tuesday by the delivery of an excellent address by the President, Mr. T. B. Groves, who congratulated the members on meeting once more at the same time and place as the British Association. The address touched on all the points of interest which have claimed the attention of chemists and druggists during the past year. We are glad that the meeting has proved such a successful one. The Association now numbers over 3000 members, and is a powerful and respected body.

ETHER v. CHLOROFORM.

Apropos of the recent discussion on this subject, we find in the last annual report on the Marine Hospital Service of the United States, that, in operations requiring the use of anæsthetics, the relative frequency of the employment of chloroform was 52 per cent., of ether 35 per cent., and of chloroform and ether combined 13 per cent. So that, in spite of what has been recorded, ether is by no means exclusively used as an anæsthetic in the United States of America.

DR. MOUAT and Mr. Henley, Poor-law inspectors, recently held an inquiry regarding a complaint made by the Wimbledon Local Board, that certain paupers suffering from scarlet fever were discharged from the Kingston Workhouse before the danger of infection was over. The Local Government Board have now addressed a letter to the Kingston guardians, stating that the complaint of the local authority has been established. The medical officer is blamed for laxity of supervision, and is admonished to be more vigilant in the future. We would here caution medical officers of union houses against permitting scarlet fever patients to leave the institution until the desquamating stage of the disease is over.

IT is well known that a large number of the Rifle Volunteers were formed into "provisional battalions" to take part in the recent military manœuvres at Aldershot. Presumably all the men were of a stamina and training somewhat above the average of their brethren, so it will perhaps surprise many who have an exaggerated faith in the Volunteer force to learn that a great number of them suffered very severely from exposure to the sun and from the by no means excessive marching which they underwent. Swollen faces and sore eyes might be seen in the ranks, while a few ingenious men wore paper masks to protect themselves from the sun.

THE *Metropolitan* states that several cases of enteric fever have occurred lately among men exposed to sewer-gas. It may be remembered that some time back the Metropolitan Board of Works issued circulars to all the parishes in London, asking for a return of any cases of zymotic disease amongst workmen employed in the sewers. We have no doubt that patient and systematic investigation in this direction would reward anyone with the necessary time at his disposal, and result in the collection of valuable data.

THE remains of Mr. A. W. Gage, surgeon, who had been a Volunteer medical officer since the year 1860, were interred in Paddington cemetery on Saturday last, in the presence of about 400 members of his regiment (the 36th Middlesex Rifles), who accompanied the funeral *cortège* from the deceased gentleman's house in St. John's-wood. Such a demonstration is gratifying to the profession generally, and must be a source of consolation—albeit mournful—to Mr. Gage's friends.

IN London 1453 deaths were registered last week, including 1 from small-pox, 27 from measles, 59 from scarlet fever, 9 from diphtheria, 68 from whooping-cough, 18 from different forms of fever, and 181 from diarrhœa. Different forms of violence caused 64 deaths. The Asylum District Fever and Small-pox Hospitals at Homerton and Stockwell contained 235 patients on the 21st inst., of whom 168 were under treatment for scarlet fever.

WE last week recorded in our "Obituary" column an instance of longevity. It related to the decease of Mr. James Snow, of Atherstone-place, Lincoln (Member 1802, Fellow 1844, Royal Coll. Surg. Eng.), in his ninety-fifth year. Mr. Snow was also a Justice of the Peace for Lincoln. The attainment of such an age in the profession, if not without precedent, is, to say the least, exceptional.

IT appears that the ship reported in THE LANCET as having arrived at San Francisco with a scurvy-stricken crew belongs to North Germany. An official inquiry was ordered last week as to an outbreak of scurvy that occurred on board a British vessel on the passage from Lagos to London.

The horses of the London General Omnibus Company are suffering from a strange and fatal malady. The disease appeared first among the horses employed in the Paddington district. It has been stated that in one stable alone twenty valuable animals lay dead on the same day, while at present there are over 200 affected. So far no explanation whatever has been given of the cause of the outbreak. A thorough inquiry into the whole matter should be made by experienced veterinary surgeons, and we might mention the name of Mr. G. Fleming as a gentleman whose services might prove valuable.

We publish this week an obituary notice of the late Dr. Toler Maunsell, of Dublin. The deceased gentleman was an indefatigable and successful advocate of the claims of the Irish Poor-law medical service, which body of men may now well show in some manner their sense of indebtedness to him, and record in a practical manner the estimation in which he was held. Dr. Maunsell was for some time the Dublin correspondent of The Lancet, and many of his letters dealing with the cause with which he had so long associated himself will now recur to our readers.

SANITARY NOTES AND REPORTS.

Mr. Alex. Winter Blyth, medical officer of health to the Okehampton Rural Sanitary Authority, has recently presented an annual report to his committee, which is chiefly noteworthy as containing some interesting particulars in connexion with epidemic pneumonia. This disease has been specially prevalent and very fatal in the Okehampton district, and the evidence adduced by Mr. Blyth goes to prove that the disease was in these cases undoubtedly infectious. Dr. Christian Budd reminds the author that he (Dr. Budd) many years ago recognised pneumonia as a blood disorder capable of being propagated by contagion. As one means of preventing this, Dr. Budd has always systematically disinfected the sputa, and relied also very much upon isolation and free ventilation, keeping bedroom windows open all the night. It is well that the attention of health officers should be directed to this subject, because it appears to have attracted little notice beyond the limits of the south-western counties. The report above quoted records nothing about water-supply, hospital accommodation, vaccination, and other subjects included in the routine work of a medical officer of health. It is right that the sanitary authority should be furnished with such particulars and short practical deductions drawn therefrom. These are even more important than a popular description of epidemic diseases.

Mr. Haviland, in presenting a special report to the Urban Sanitary Authority of Northampton for the years 1873–4, is able to offer congratulations on a decline in the average percentage of mortality. Deaths of children were exceptionally high in this town during the ten years 1861–70, those due to diarrhœa amounting to 10·9 per 1000, or nearly double the percentage for England and Wales. Small-pox was 2·4 per 1000 in excess, scarlet fever 2·6 in excess, measles 2 in excess, and diseases of the respiratory organs (including phthisis) 1·9 in excess, as compared with the whole country. During the years under consideration, the mortality has, as was remarked above, lessened considerably, and is accounted for by the fact "that during these later years the Northampton Water Company's deep well of 163 feet in the marlstone has supplied water to the inhabitants instead of the shallow wells, which for ages had frequently become polluted by their close proximity, in the porous ironstone, to filthy receptacles of sewage of every description." All supplies from superficial sources are now cut off, and during the past two years the mortality of Northampton from the seven principal zymotic diseases has, as compared with the preceding periods above quoted, declined considerably, the borough death-rate being below the average English death-rate, and considerably below the average for town districts. These records as to Northampton are specially noteworthy, as showing conclusively the important influences exercised by a good water-supply.

The second Report on the sanitary condition of certain districts in Oxfordshire, prepared by Dr. Gilbert W. Child, medical officer of health, has recently been issued. The author commences by recording that "sanitary statistics, as we are at present able to obtain them, are utterly useless for every scientific purpose, and, indeed, not only useless but misleading." Scarlatina and diphtheria, typhoid and diarrhœa, are mixed up together. "Slow fever," "general break-up," and "diuresis," are among the causes of death found in registers. The statement that a man died of "erysipelas (fourteen days), typhoid fever and exhaustion (seven days)," is somewhat puzzling; as also "diabetes, typhoid fever (fourteen days)," where no history of typhoid could in either case be obtained. The importance of obtaining early information as to the existence of epidemics is strongly insisted upon, and the author thinks that a legal obligation should be laid upon every householder to give notice within forty-eight hours of the occurrence of any case of infectious disease within his house. (This plan, by the way, is adopted, and very successfully, in Holland, and the house is then, as it were, quarantined, by placing a conspicuous card in the window.) Dr. Child inveighs against the practice of ventilating sewers by openings into the streets at the road level, conspicuous examples of which exist, as he says, at Oxford. It is argued, therefore, that a well-laid, open street gutter is, after all, in country villages, the best system of drainage "which our present knowledge enables us to devise." The Report, which is admirably compiled and unexceptionably got up, contains a variety of information and discursive matter well worthy the attention of urban and rural officers of health.

Correspondence.

"Audi alteram partem."

CHLOROFORM OR ETHER.

To the Editor of The Lancet.

Sir,—The statement contained in Dr. Hodges's letter, published in The Lancet of the 14th inst., to the effect that in March last I had abandoned ether as an anæsthetic, in consequence of having lost several patients from its use, requires to be modified.

It is true that at the time mentioned I had discontinued the employment of ether, my reasons being mainly as follows:—(1st) In my own practice I had observed in several instances after its use a bronchial attack extending over a variable number of days, which may, perhaps, be best described as one of suffocative catarrh; (2nd) my colleague, Mr. Wheelhouse, informed me that he, too, had met with similar effects, and that one patient under his care had died of acute bronchitis; and (3rd) in a few instances the administration of ether had been followed by violent maniacal excitement. One patient, upon whom an operation for strangulated hernia had been performed, in his frenzy tore the wound open and dragged out a large loop of intestine. Thus, because my comparatively small experience of ether had afforded such unfavourable testimony, I deemed it prudent to wait for further information, and meanwhile to fall back upon chloroform, from which in nearly twenty years I have met with but one death.

In administering ether our chief object had always been carefully to prevent any dilution of the vapour with air. The apparatus we used was a large sponge covered, except at its mouth, with impermeable cloth. Two or three ounces of ether having been poured into the hollow, the sponge was forcibly pressed over the nose and mouth of the patient, and there retained, with a momentary removal only when the ether required to be renewed until anæsthesia was complete.

After an interval of a few months we are now again using ether, but, by simply pouring it upon a folded towel held closely over the nose and mouth, air is admitted along with the vapour. As yet it is too early to speak of results. Two cases within the last few weeks have given me uneasiness.

On the 1st of this month I was asked by Dr. Allbutt and Mr. Holmes to perform lumbar colotomy upon a patient whom they were jointly attending. Ether was administered by Mr. M'Gill. Nothing could be more satisfactory than the patient's condition during the operation. As soon, however, as sensibility returned a sense of suffocation overpowered all other feelings, and it was not until the third or fourth day after operation that our anxiety on account of his breathing was removed. Even now, at the end of three weeks, he complains of wheezing and cough. Prior to the operation he had been absolutely free from all chest symptoms.

The other case, though perhaps open to exception, is worthy of mention. On the night of the 13th inst. I removed, at the Leeds Infirmary, an extra-uterine fœtus at about the eighth month, by abdominal section, the mother being under the influence of ether. The child, whose movements had previously been of the most lively order, was readily extracted, and separated in the usual manner. The mother did not suffer in any untoward way from the effect of the ether. The baby, well-formed and vigorous, had a desperate struggle for existence, extending over fully an hour, in consequence of imperfect respiration. Mr. Hey has since suggested that the ether was probably responsible for this, and I think the suggestion a reasonable one.

Notwithstanding these somewhat unfavourable beginnings, it is my intention, in deference to the experience of others, to give ether an extended and careful trial. As yet I am not prepared to say more than that I am not convinced of the superiority of ether over chloroform. I will only add that, after a large experience of its use, I entertain a great respect for chloroform, which has been in no wise lessened by the recent indiscreet utterance regarding it.

Although, unhappily, many deaths have occurred, some of which, indeed, have been as unavoidable as they were unforeseen, I am fully convinced that if proper care and competent knowledge be brought to bear in every case in which chloroform is given, fatal consequences will be few and far between.

I am, Sir, your obedient servant,

Leeds, August 24th, 1875. T. R. JESSOP.

To the Editor of THE LANCET.

SIR,—I trust that, in any future comprehensive estimate of the dangers of chloroform inhalation, the mode of its administration will be appended to the actual number of fatal cases. It will be interesting to know how far experience bears out Mr. Pollock's confident denunciation of the "rough and ready method," and the great comparative safety of certain special modes of procedure. For my own part, I am thoroughly convinced of the practical truth of Mr. Syme's teaching in this important department of surgery, and should always prefer to give chloroform very freely by means of towel or handkerchief, to press the inhalation boldly during the stage of violence, and to look specially to interference with respiration as the leading cause of danger. However retrograde these views may be considered in many quarters, they are amply borne out by Edinburgh experience, which can point to by far the most extended and satisfactory use of chloroform anæsthesia with which we are acquainted. Without in any way wishing to deny the admirable skill and tact possessed by Mr. Clover, I may venture to remind visitors to the Royal Infirmary of Edinburgh of the way in which chloroform is there given with great freedom by house-surgeons and dressers—who have in no measure devoted themselves specially to the subject; and the safety of its use there, as well as all over Scotland, can hardly be denied. Herein then lies one advantage of chloroform, that whilst its use may be entrusted to competent professional men who are not specially instructed in its administration, ether requires to be given by practised hands before efficiency can be secured and discomfort avoided.

You, Sir, are doing good service by endeavouring to check the somewhat dogmatic assertions of those who preach the absolute safety of ether. Experience is not sufficiently extended either to settle this point or the relative advantages of one anæsthetic over another; still less desirable would it be to encourage at this stage of the proceedings any attempt at interference on the part of superficially instructed public opinion.

Let us remember the remarkable way in which safety seems to attend the early history of any anæsthetic agent, of the vaunted immunity from danger of bichloride of methylene which experience has failed to confirm, of the remarkably few deaths which attended the first few years of chloroform. Ether, in our own country at least, has not yet emerged from this period, and American experience can hardly fail to be tinged with the prejudice of controversy; and, although Mr. Carter's friends have been so unfortunate in their practice, I may refer to the recorded experience of two surgeons of probably equal eminence, Professor Syme and Professor Gross, the former of whom caused the administration of chloroform in nearly 4000 cases, and the latter in 6000 cases, without inconvenient result.

I am, Sir, your obedient servant,

ROBERT FARQUHARSON, M.D.

Pinzean, Aboyne, Aberdeenshire, Aug. 1875.

To the Editor of THE LANCET.

SIR,—You will no doubt permit me to supplement your valuable remarks on the relative merits of ether and chloroform with a few further particulars, derived from personal knowledge, of the experiences of the late Mr. Robinson on this important question. You do not appear to be aware of the fact that a second death occurred from the administration of ether in Mr. Robinson's practice, and to this I attribute his relinquishment of it almost immediately on the introduction of chloroform. If my memory serves me rightly, it was about the beginning of the year 1850 that a middle-aged gentleman called upon Mr. Robinson one morning for the purpose of having a tooth extracted without pain. Ether was administered with an inhaler in his usual operating chair, and in the presence of an assistant. The patient was soon apparently under its influence, but just as Mr. Robinson was on the point of applying the forceps the under jaw dropped, and a deadly pallor came over the face. The gentleman was quickly removed to the floor, and the servants sent off for assistance. I, being then a next-door neighbour, was quickly on the spot, soon to be followed by the late Dr. Booth, also a neighbour. Every effort was made to restore animation, but without effect.

The death of this patient gave a great shock to my friend Mr. Robinson, who determined from that moment never again to administer ether or any other anæsthetic to a patient, except in the presence of a member of the profession. He also at once set himself to work to determine the relative merits of ether and chloroform, and, in conjunction with Dr. Booth and myself, a large number of experiments were tried on dogs, cats, rats, &c. Ultimately the conclusion was arrived at — so far as the lower animals could be taken as a safe guide and test — that chloroform was by far the safer anæsthetic of the two. The precise statistics of deaths I am at this period of time unable to furnish, but since then I have largely employed and administered chloroform as well as bichloride of methylene in eye operations on the most tender infants and adults of all ages, some exceeding fourscore years, without a single fatal result.

I remain, Sir, your most obedient servant,

Bedford-square, Aug. 17th, 1875. JABEZ HOGG.

To the Editor of THE LANCET.

SIR,—I have watched with considerable interest the controversy which has lately been going on in the columns of THE LANCET (and other journals) on the subject of anæsthetics.

I have, during the last two years and a half, had a somewhat considerable experience in the use of such agents. I usually perform from ten to twenty or more capital operations on the eye per week. For a large majority of these an anæsthetic is given. The administrator is always one of my dressers, who, as a rule, has had little or no previous experience in producing anæsthesia. I therefore have to take whatever responsibility there may be upon myself, and, as you may suppose, it has been my aim to find a safe and effectual agent.

I have, with the exception of nitrous oxide gas, tried all the anæsthetics that have ever come generally into use. These include chloroform, bichloride of methylene, methylene ether, ether, and a mixture of chloroform, alcohol, and ether. My experience has brought me to the conclusion that none are, or even approach to being, *absolutely* safe. Moreover, I do not see how any agent that at first partially asphyxiates a person, then renders him violent, and finally places him in a comatose condition, can be administered without some spice of danger.

I have seen patients apparently on the verge of dissolution from each of the anæsthetics I have mentioned, but only once has it been my lot to have one die under my hands. The anæsthetic used in this case was called methylene ether, but I believe its composition is somewhat doubtful. The patient was a fine young woman, aged twenty-eight. She suffered from exophthalmic goitre. The operation contemplated was for the diminution of the palpebral aperture in each eye; its object to prevent exposure of the corneæ, as the eyes were so prominent that they could not be kept closed except by an effort. The operation had been completed on one side, and was about to be commenced on the other, when the patient died as suddenly as if shot. The usual restorative measures were resorted to with the usual result. A post-mortem examination revealed (with the exception of enlargement of the thyroid gland) no disease whatever.

This case was the twenty-second that had taken the same anæsthetic on the same day, and in no other had any alarming symptoms occurred. Now, why some persons die from anæsthetics I do not know; that anyone may be killed by any of them I do not doubt; but I feel certain that there is in some an "idiosyncrasy" rendering them incapable of taking anæsthetics with safety. I believe that had my patient taken the reputedly harmless ether, or any other anæsthetic, the result would have been the same. I used the methylene ether for some time after without any bad results.

I then went back to what I had been in the habit of using previous to the methylene ether—viz., bichloride of methylene for short operations and chloroform for larger ones. Occasionally unpleasant symptoms occurred.

I next tried ether, with the result that I have made up my mind never to use it again if I can get anything else. To say nothing of its disagreeable smell, its action is most unsatisfactory, and unless given by an experienced administrator most uncertain; and, as far as the production of apparently dangerous symptoms goes, it equals, if it does not surpass, all other anæsthetics. I much doubt its safety, and, as far as I am concerned, it will have very little chance of asserting its superiority in this respect over other agents. For the last eight months I have used almost exclusively the mixture of chloroform, alcohol, and ether recommended by the Committee of the Royal Medico-Chirurgical Society. I am well satisfied with it—in fact, I like it better than any anæsthetic I have yet tried; but, as with the other agents, I have seen alarming symptoms occur more than once, and very probably I shall sooner or later meet with a patient who has the peculiar intolerance of anæsthetics, and he or she may die on the table. That that day may be far distant I sincerely trust. Deaths have occurred and may occur again from all the anæsthetics at present in use, in spite of all our care, and I think that their relative safety yet remains to be determined.

Yours faithfully,

CHARLES HIGGENS, F.R.C.S.E.,
Assistant Ophthalmic Surgeon, Guy's Hospital.

Brook-street, W., August 14th, 1875.

THE CASE OF GENERAL REECE, C.B.

To the Editor of THE LANCET.

SIR,—While fully concurring in the main facts as stated by Dr. Tuke in your journal of last week on the above subject, I should wish to correct a clerical error as to the date which he gives as that of General Reece's death. The General died on August 1st, not July 12th, as stated. Dr. Tuke does not mention, and perhaps does not know, that my attendance on General Reece was not through the instrumentality of his sons, as stated in your leading article of the 14th inst., as I was an utter stranger to them. Mr. Low called in Dr. Wilks, who suggested that I should be sent for, and accordingly Archdeacon Reece brought me at once to the house of my late patient. Mr. Low I then met for the first time, and he expressed a wish to me to take the General under my medical care, at the same time saying, "he would write to Dr. Sillifant a letter of explanation and send him a cheque for his attendance," as otherwise, I said, I could not take the patient under my charge. I must also remark that it was entirely through the General taking a bitter hatred to the nurses, notwithstanding their kindness and attentions to him were most unremitting, that they were discharged, and not from any wish on the part of the sons. In noticing the carpetless room of General Reece, Dr. Tuke was not probably aware that there had been some carpet down, but it was obliged to be destroyed, and was nailed down by numberless tacks, and was in almost as many pieces.

I am, Sir, your obedient servant,

FREDK. G. BROXHOLM.

Richmond-road, Barnsbury, N., August 24th, 1875.

THE PROPOSED MEETING OF THE BRITISH MEDICAL ASSOCIATION AT BRIGHTON IN 1876.

To the Editor of THE LANCET.

SIR,—The accompanying letter was sent last week to the *British Medical Journal*, but not inserted. Would you kindly give it publicity through your columns?

"With reference to the above object may I be allowed to ask, through the medium of your *Journal*, if the Council of the Association, and other parties concerned, are aware that the great majority of the medical men of the town are opposed, under present circumstances, to any such meeting? My impression is that if the opinion of the profession were now taken upon the question three-fourths would be found to give their votes against it. It is very true that a memorial was got up inviting the Association to hold their next meeting at Brighton, but it was not numerously signed; while there was also a counter-memorial containing the names of many of the leading medical men of the place. I have, moreover, strong grounds for stating that many of those who did sign the memorial in favour of the meeting, upon consideration, look upon the movement as ill-considered and hastily got up."

I am, Sir, your obedient servant,

WILLIAM KEBBELL, M.D.

Upper Brunswick-place, Brighton, Aug. 23rd, 1875.

MORTALITY AFTER PRIMARY AND SECONDARY OPERATIONS.

To the Editor of THE LANCET.

SIR,—Will you allow me to draw attention to a statement in Mr. Erichsen's "Science and Art of Surgery," on p. 35 of the fifth edition, which is as follows:—"In civil practice the mortality after primary amputations, as will be seen by the preceding table, somewhat exceeds that following secondary operations." Now, in the tables to which he refers, singularly enough, the mortality is decidedly *less* in primary than in secondary amputations. Thus, in the first table there are 475 cases of primary amputations, with 147 deaths, and 163 secondary amputations, with 84 deaths. These numbers give a mortality for primary amputations of 30 per cent., and for secondary amputations of 51 per cent. In the second table there are 48 primary amputations, with 18 deaths, and 43 secondary, with 19 deaths, or a mortality of 37 per cent. in primary and of 44 per cent. in secondary amputations. Both tables, therefore, pronounce in favour of *primary* amputations and not of *secondary*, as Mr. Erichsen asserts. Some explanation of this seems desirable, especially as he repeats his assertion on p. 128 of the same work.

I am, Sir, yours truly,

August 16th, 1875. R. R.

*** We doubt not that Mr. Erichsen will be glad to have his attention called to the mistake referred to. If our correspondent consult the last edition of Mr. Erichsen's work he will find the statement considerably modified.—ED. L.

"IMPERFECT MEDICAL QUALIFICATIONS."

To the Editor of The Lancet.

Sir,—In reading, in this week's Lancet, your paragraph on "Imperfect Medical Qualifications," I could not help noticing the one-sided and imperfect statements made on the subject. The form of registration is most important and necessary, and that point may be dismissed. I wish to refer to the apparently defective "one qualification" system, and to inquire what is the real difference between a man with one qualification and another with two? I am unable to find any. You are at liberty to bring forward any man with two qualifications and it will be found that my *medical* and *surgical* training have been almost identical with, if not more ample than, his. If the training of a physician and surgeon are alike, as they must necessarily be, why require two diplomas? It is quite farcical to require such, and delusive to the public, who fancy that a physician must be a more learned man than an ordinary surgeon, who perhaps went through the *same* school, class for class, with the former as his companion. The remedy is to unite the Colleges of Physicians and Surgeons, and, as they have one curriculum, let them have one diploma for both, instead of being opposition shops.

I am, Sir, yours, &c.,

Manchester, Aug. 21st, 1875. L.F.P.S.

⁂ Our correspondent's question is one we have often given the answer to in our articles on the one-portal system. What is the real difference between a man with one qualification and another with two? We answer, practically none. Both have been educated alike, and, what is more, both have been examined alike. The man with a medical qualification has been examined in surgery, and *vice versâ*. But after all there is a real difference. It is this:—That the man with two qualifications has paid double fees, and given support to two corporations; while the man with one has given support to only one. About a hundred years after this we shall have one College of Medicine, or some tantamount institution, giving a complete diploma after a fair examination. Meantime corporations must be maintained, and candidates who would be fully qualified must pass two identical examinations. And men of the eminence of Sir Robert Christison will defend the system.—Ed. L.

Obituary.

D. TOLER T. MAUNSELL, M.B., M.R.I.A., &c.

Daniel Toler Thomas Maunsell died on the 18th of August, after a short illness, at his residence, South Richmond-street, Dublin, at the comparatively early age of forty. He was the eldest son of the late Rev. Thomas Maunsell, of Fintona, Co. Tyrone. He graduated with distinction at Trinity College, Dublin, where he obtained the degree of Bachelor of Medicine. He held the licence of the Royal College of Surgeons in Ireland, and had also a licence in Midwifery. Dr. Maunsell was a member of the Royal Irish Academy, and successively held the posts of Demonstrator of Anatomy in the Carmichael School of Medicine, of lecturer on Materia Medica in the Ledwich School, and lastly that on Botany in the same school. He was for several years one of the medical officers of the South City Dispensary (Dublin), and since the beginning of October, 1874, was sanitary officer for his division of the South City District.

Dr. Maunsell was deservedly popular from his kindly, genial disposition. For several years he wrote much and effectively on the importance of the Poor-law medical service. He drew attention to the powerful effect of timely medical aid in the reduction of pauperism, and showed that much of the latter owed its origin to sickness. With other members of the Irish, as well as with many of his brethren on this side of the Channel, Dr. Maunsell laboured to obtain a better recognition of the important services of the Poor-law medical officers in both countries. He always maintained the necessity of providing a certain retirement for the medical officers when disabled from further service by age or ill-health, in lieu of that now dependent on the will or caprice of boards of guardians.

Dr. Maunsell leaves a widow and six young children to lament his loss.

WILLIAM HEY, F.R.C.S. Eng.

Mr. Hey belonged to a family celebrated in the history of surgery, his grandfather and his father having long practised in Leeds. He himself became M.R.C.S. Eng. as far back as 1818, and a Fellow in 1843, and was the oldest practitioner in the town, of which he was one of the celebrities. Like his grandfather and father, he was for a great number of years on the surgical staff of the Leeds Infirmary, which the first Hey was largely instrumental in founding. On his father dying, in 1844, he succeeded to the practice. He was associated with Mr. Samuel Smith, Mr. Joseph Prince Garlick, Mr. Wm. Price, and other well-known surgeons in the town, all now numbered with the dead, in founding the Leeds School of Medicine, and his was a familiar face in the lecture theatre. He was lecturer on surgery from the year 1831 to 1857, since which time he had been an honorary member of the Council. Amidst the cares of his profession, and although devoting much time to music and scientific pursuits, Mr. Hey in his early manhood took an interest in politics. On the passing of the Municipal Corporations Reform Act, he came forward as one of the Conservative candidates for the Mill-hill Ward, and was returned at the head of the poll. He was a Deputy Lieutenant and a Justice of the Peace for the West Riding of Yorkshire, and his name also appeared on the commission for Leeds, but he never qualified for the borough. He died on the 10th of May, aged seventy-eight.

Medical News.

University of London.—The following is a list of the candidates who have passed the recent 1st M.B. examination in Honours:—

Anatomy.

SECOND CLASS.

Miller, Richard Shalders, } University College.
Bury, Judson Sykes,
Benham, Frederick Lucas,

Physiology, Histology, and Comparative Anatomy.

FIRST CLASS.

Henderson, George Courtenay (Exhibition and Gold Medal), University College.

SECOND CLASS.

Benham, Frederick Lucas, University College.
Wilkinson, Arthur Thos., B.A., B.Sc., Owens College.
Pye, Walter, St. Bartholomew's Hospital.
Stevenson, Leader Henry, Guy's Hospital.
Miller, Richard Shalders, University College.

THIRD CLASS.

Sedgefield, Arthur Robert Wyatt, King's College. } Equal.
Willcocks, Frederick, King's College.
Hudson, James, University College. } Equal.
Wiglesworth, Joseph, Liverpool School of Medicine.

Organic Chemistry, and Materia Medica and Pharmaceutical Chemistry.

FIRST CLASS.

Wilkinson, A. T. (Exhibition and Gold Medal), Owens College.
*Henderson, G. Courtenay (Gold Medal), University College.

SECOND CLASS.

Goodchild, Francis, St. George's Hospital.

THIRD CLASS.

Miller, Richard Shalders, University College.

* Obtained the number of marks qualifying for the Exhibition.

British Medical Service.—The following is a list of gentlemen who competed successfully for appointments in the above Service at the examination held at the University of London on Aug. 9th:—

	Marks.		Marks.
Hewett, F. C. C. ...	2367	Daubeny, C. A. ...	1775 }
Taaffe, R.	2132	Ievers, P. G.	1775 }
Le Grand, W. J. ...	2050	Burges, W. A. ...	1720 }
Briggs, W. H. ...	1855	Fleming, H. B. ...	1720 }
Fenn, E. H.	1825 }	James, W. M.... ...	1618
Kellett, L. H.... ...	1825 }	Hayes, P. A.	1540
Thompson, T. W....	1785	Kirkwood, K. D. L.	1450
Findlay, J.	1780		

Indian Medical Service.—The following is a list of candidates who were successful at the competitive examination held at Burlington House on Aug. 9th:—

1. Freyer, P. J.
2. Weir, P. A.
3. Haig, P. de H.
4. Lewtas, John.
5. Ferrand, Edward.
6. O'Neill, John.
7. Pedrona, F. H.
8. Clarkson, J. W.
9. Day, C. H.
10. Parker, —.

Thirty candidates competed for ten appointments. All were reported qualified.

Apothecaries' Hall. — The following gentlemen passed their examination in the Science and Practice of Medicine and received certificates to practise on Aug. 19th:—

Bruce, Robert, Old-street, St. Luke's.
Chant, Thomas, Bridgewater.
Clark, William Theobald Blanton, Malmesbury, Wilts.
Joseph, Sidney Westbrook Jorwerth, St. Leonard's-on-Sea.
Willans, William Blundell, Singapore.

The following gentlemen passed the Primary Professional Examination on the same day:—

James, Thomas, Middlesex Hospital.
Morris, Clarke Kelly, St. Thomas's Hospital.

The Library of the Royal College of Surgeons will be closed as usual during the month of September, for the necessary repairs and cleaning.

The Local Government Board have awarded a vaccination gratuity to the representatives of the late Dr. Wilton Provis for his efficient performance of vaccination in the district of the Mere Union.

Coombe Lying-in Hospital, Dublin.—The annual report of this hospital for last year shows that 411 labour and chronic cases were attended to in the hospital, 1224 labour cases at their own homes, and 19,252 cases of diseases of females and children were visited at their own homes and supplied with medicine, making a total of 20,887. The new building is progressing favourably, and the institution received during the past year a bequest of £250 from the late Mr. Findlater, and upwards of £500 from the Hospital Sunday Fund. The total income from private and public sources was £2273 16*s.* 1*d.*, and the expenditure of the establishment £1138 17*s.* 10*d.* The total number of patients in hospital during the year was 17,210.

Bequests, &c., to Medical Charities.—Miss Susanna Garmston, of Grimley, has bequeathed £5000 to the Worcester Infirmary, and £1000 to the Worcester Dispensary. The Hereford General Infirmary has become entitled to £1000 under the will of the Rev. H. C. Morgan, of Goodrich. Mrs. Hitchman, of Fenton House, has given £700 (£400 as from her sister, the late Miss Baker, and £300 as from herself) to the North Staffordshire Infirmary, and £300 to the Longton Cottage Infirmary. The Brighton Hospital lately received a legacy of £500 and a large quantity of books. The Worcester Infirmary has received £500 under the will of Mrs. Jane Barton, of Weston-super-Mare. The Marchioness of Westminster has made a second donation of £200 in aid of the enlargement fund of the Royal Infirmary for Children and Women, Waterloo-bridge-road.

Medical Appointments.

Barham, H. F., M.R.C.S.E., has been appointed Assistant Visiting Surgeon for Maidstone, under the provisions of the Contagious Diseases Acts (Women), vice Broughton, resigned.

Bayliffe, A. M., M.R.C.S.E., has been reappointed Medical Officer of Health for the No. 4 Sub-district of the Axbridge Rural Sanitary District for two years.

Blackall, J. J., M.D., C.M., has been appointed Assistant to the Medical Superintendent of the Richmond District Lunatic Asylum, Dublin, vice Petit, appointed Resident Medical Superintendent of the Donegal Lunatic Asylum, Letterkenny.

Burness, A. G., M.B., C.M., has been appointed Physician to the North London Hospital for Consumption and Diseases of the Chest.

Caddy, H., M.R.C.S.E., has been appointed Senior House-Surgeon to the Royal Southern Hospital, Liverpool, vice W. Williams, M.D., M.R.C.P., resigned.

Carter, F. H., M.R.C.S.E., has been appointed House-Surgeon to the Great Northern Hospital, vice Irving, resigned.

Collins, H. W., M.R.C.S.E., has been reappointed Medical Officer of Health for the No. 2 Sub-district of the Axbridge Rural Sanitary District for two years.

Corbet, D., M.R.C.S.E., has been reappointed Medical Officer of Health for the Kidderminster Urban Sanitary District for two years.

Doran, A. H. G., F.R.C.S.E., has been elected Surgeon to the Westminster General Dispensary, vice W. Rose, F.R.C.S.E., resigned.

Doyle, C. W., M.B., C.M., has been appointed Resident Medical Officer to the Norfolk and Norwich Dispensary, vice Bagnall, resigned.

Ford, J., M.R.C.S.E., has been reappointed Medical Officer of Health for the No. 3 Sub-district of the Axbridge Rural Sanitary District for two years.

Fowler, G., M.R.C.P.Ed., has been appointed Physician to the North London Hospital for Diseases of the Chest.

Griffiths, J. T., L.R.C.S.Ed., L.F.P. & S. Glas., has been appointed Medical Officer and Public Vaccinator for the Llandwrog District of the Carnarvon Union, vice Williams, resigned.

Gwatkin, O., M.R.C.S.E., has been appointed Junior House-Surgen to the Royal Southern Hospital, Liverpool.

Hullah, R., M.R.C.S.E., has been appointed Surgeon-Superintendent of the Eastern Province Asylum for the Insane, Graham's Town, Cape of Good Hope.

Humphreys, J. H., M.D., M.R.C.S.E., has been appointed a Surgeon to the Hastings Dispensary, vice Allen, resigned.

Jones, A. E., M.B., C.M., has been appointed Resident Medical Officer to the Hulme Dispensary, Manchester, vice J. Walker, M.B., resigned.

Morris, D. W., L.K.Q.C.P.I., M.R.C.S.E., has been appointed Medical Officer and Public Vaccinator for the Kentchurch District, and Medical Officer to the Workhouse of the Dore Union, Herefordshire, vice Lane, resigned.

O'Honlon, W. P., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer to the Ipstones Court No. 809 of the Ancient Order of Foresters, vice Hamilton, resigned.

Palmer, A. M., M.R.C.S.E., has been appointed Medical Officer and Public Vaccinator for the Whittington District of the Chesterfield Union, vice France, deceased.

Popham, S. L., M.B., C.M., has been appointed Medical Officer and Public Vaccinator for No. 1 District and the Workhouse of the Daventry Union, vice Gibson, resigned.

Price, A., L.S.A.L., has been appointed House-Surgeon to the Westminster Hospital, vice Davies, whose appointment has expired.

Ralfe, C. H., M.D., M.R.C.P.L., M.R.C.S.E., has been appointed Teacher of Physiological Chemistry at St. George's Hospital Medical School, vice Moore, deceased.

Reid, D. A., M.D., M.R.C.S., has been appointed Consulting Surgeon to the Pembroke and Pembroke-dock Dispensary and Infirmary; also Admiralty Surgeon and Agent to the Tenby District, and Surgeon to the Trinity Board in the same district, vice Utterson, resigned.

Reoch, J., M.B., C.M., has been appointed Professor of Physiology at the University of Durham College of Medicine, Newcastle-on-Tyne, vice Nicholson, appointed Professor of Botany and Natural History at the University of St. Andrews.

Sherburn, J., M.B., C.M., has been appointed Resident Assistant-Surgeon to the Hull General Infirmary, vice Sinclair, resigned.

Smith, J. O., L.R.C.P.Ed., L.M., M.R.C.S.E., has been appointed Medical Officer and Public Vaccinator for the St. Chad District of the Atcham Union, Salop, vice Willett, deceased.

Wade, C., M.R.C.S.E., has been reappointed Medical Officer of Health for the No. 1 Sub-district of the Axbridge Rural Sanitary District for two years.

Walsh, T. W., F.R.C.S.E., has been reappointed a Surgeon to the Worcester General Infirmary, upon the expiration of his second term of office under the rules.

Wimpenny, J., M.R.C.S.E., has been reappointed Medical Officer of Health for the Upper-Thong Urban Sanitary District for two years.

Births, Marriages, and Deaths.

BIRTHS.

Harvey.—On the 19th inst., at Upper Merrion-street, Dublin, the wife of R. J. Harvey, M.D., of a daughter.

Menzies.—On the 13th inst., at Naples, the wife of J. A. Menzies, M.D., of a son.

Noad.—On the 16th inst., at Wokingham, the wife of G. W. Noad, M.D., of a daughter.

Page.—On the 16th inst., at Kendal, the wife of David Page, M.D., of a son.

Pullar.—On the 21st inst., at Kensington-park-gardens, the wife of Alfred Pullar, M.D., of a son.

Watson.—On the 17th inst., at Penistone, the wife of Alfred M. Watson, M.D., of a son.

MARRIAGES.

Hoops—Robinson.—On the 9th inst., at Trinity Church, Dublin, Samuel E. Hoops, L.K.Q.C.P.I., to Harriette, daughter of the late Thomas Robinson, Esq.

Wills—Watkins.—On the 17th inst., at the Parish Church, Brighton, Charles James Wills, M.D., to Alice Lucy Watkins, widow of D. R. Watkins, Esq.

DEATHS.

Cocks.—On the 19th inst., at Yew-bank, Broughty-ferry, Dundee, Robert Cocks, M.D., aged 64.

Cutliffe.—On the 22nd inst., at Lambeth-square, Chas. Newell Cutliffe, M.R.C.S.E., aged 70.

Finney.—On the 8th inst., at Ockbrook, Derbyshire, Charles White Finney, L.S.A.L., aged 61.

Fleming.—On the 21st inst., at Buxton, Alex. Fleming, M.D., of Birmingham, aged 51.

Jones.—On the 18th inst. (suddenly), at Orford House, St. John's-road, Brixton, S.W., Sydney Felix Orford (infant son of J. T. Jones, L.K.Q.C.P.I., L.M., M.R.C.S.E., of Llanfyllin, Montgomeryshire, and St. John's-road, Brixton, London), aged 9 months.

Naismith.—On the 18th inst., at Hamilton, Wm. Naismith, M.D., aged 50.

Parkinson.—On the 10th inst., at Wimborne-Minster, Dorsetshire, Chas. B. Parkinson, M.R.C.S.E., aged 63.

Pilkington.—On the 18th inst., at Chorley, Wm. Pilkington, L.R.C.P.Ed., aged 45.

Webb.—On the 10th inst., at Kilburn, Thos. E. Webb, M.R.C.S.E., aged 72.

Notes, Short Comments, and Answers to Correspondents.

Prejudice against Mortuaries.

The force of public opinion is strongly urging upon urban sanitary authorities the necessity of providing mortuaries for the use of the poor who occupy one or at most two rooms, more especially in cases of deaths from zymotic diseases in crowded neighbourhoods. It is, however, easier to furnish mortuaries than to get them used by those for whom they are principally intended. It is an unfortunate fact that an ignorant impatience on the part of the poor of any interference with the liberty of the subject is one of the most serious drawbacks to the more rapid improvement in the sanitary condition of urban districts. It is satisfactory to find from Dr. Whitmore's report on the Health of Marylebone in 1874, that the local prejudice against the use of the parish mortuary is subsiding. During the year 1874 the number of bodies received in this mortuary was 58, against 31 in the previous year. The majority of bodies admitted during the year were of persons aged upwards of sixty years. The sanitary value of mortuaries in cases of deaths in crowded tenements is too generally admitted to be worth dwelling upon, and it is only surprising that they are not more frequently used, if only on the ground of convenience. Dr. Whitmore says, "I have not unfrequently seen a coffin placed on chairs in the corner of a small room, in which the whole family, numbering five or six persons, were at dinner." The duty of educating the poor to overcome their prejudice against using mortuaries is as clear as is the duty of urban sanitary authorities to provide them.

Mr. H. E. Spencer is thanked for his communication. The matter shall be rectified.

A Medical Coroner's Inquest.

To the Editor of The Lancet.

Sir,—I would ask you in a spirit of fair play to give publicity to the following facts.

On Tuesday, August 3rd, I was called to see a woman, seven months pregnant, suffering from an intense and constant pain in the lower part of the abdomen. I could find nothing else the matter with her, and she was not weak. I told the husband not to be frightened, but I did not say his wife "would be all right directly." I went at once to my partner, Dr. Masters, and asked him to give me some opium pills, containing one grain in each pill. He gave me four, and I went immediately back to the house, and told the husband to give his wife three of the pills at intervals of three hours between each pill, and to come to the surgery at 7 p.m. to let me know how she was going on. The husband came accordingly, and said he thought his wife was worse. I then gave him a mixture containing some diffusible stimulants and anti-spasmodics. The husband came next morning at 7.50. I had been up nearly all night, and was then asleep. However, I was at his house before 9 a.m. I found the woman in a dying state. She was conscious, and still complained of pain. I gave her some brandy with ten minims of tincture of opium, and had hot bottles put to her feet. I also sent for Dr. Masters to come at once, and to bring some carbonate of ammonia. Just as he came the woman died.

The next day I met the village policeman. He told me he was about to go to Buxton to see the coroner (Dr. R. Bennett) about holding an inquest. I told him I had attended the case, and that I was willing to give a certificate of the woman's death. Notwithstanding this, an inquest was held on the following day. Before I proceeded to give my evidence at the inquest, I asked the coroner's leave to make a remark. He, however, told me to answer his questions, and nothing else. After I had just begun to give my evidence, he (the coroner) turned round sharply to me, and told me to keep my hands down, and to stand up properly; that this was a very serious matter for me, and that I was taking the affair a great deal too lightly. Whereupon I remarked that it was quite unintentional on my part if my posture offended him, and I also added that he had no right to say I was taking the affair too lightly, as I was very sorry indeed for what had occurred, but that I did not think it was my fault. I then asked him if I might have a chair, but he answered simply "No." After the jury had found their verdict, "Death from syncope," the coroner sent for me, and said I had narrowly escaped from being committed for manslaughter, as there were charges of great neglect against me. I then asked him what the charges were, and he said that—

1st. The husband had called three or four times for me on the morning the woman died before I would go to see her.

2ndly. That the first day when I saw the woman at noon I took at the time some pills out of my waistcoat pocket, and gave them to the husband to give his wife.

3rdly. That it was the opinion of the jury that, in the state the woman was in, I had no right to administer the medicine I did.

I then said to the coroner that as regards the first two charges I would call Dr. Masters to prove that they were both false; but he said he would not have Dr. Masters' evidence. As regards the latter charge, I said that a jury chosen from the working class were incapable of forming an opinion on a purely medical question.

If a coroner is justified in behaving to a medical man as Dr. R. Bennett has done to me, I will always have the fear of being committed for manslaughter when I attend to a serious case in this county.

Yours obediently,
W. Chatterton, A.B., M.B., C.M. Univ. Dub.
Hayfield, near Stockport, Aug. 1875.

⁂ We make no comment at present on the above statements, which, it must be remembered, are made by an interested party. It is only fair to say that they are supported in the main by a newspaper report of the proceedings which has reached us. It is most remarkable that no post-mortem examination was ordered by the coroner, who, nevertheless, reflected severely on the treatment of the patient by the medical man.—Ed. L.

Treatment of Eczema in Children.

Dr. Caspari (*Deut. Klin.*, No. 4, 1875) states that he has never seen any good effects result from the use of mercury or iodine in chronic eczema in children. On the other hand, in cases of eczema capitis, eczema faciei, and impetigo faciei in children, he has seen the most extraordinary effects, even in obstinate and old-standing cases, follow the simple administration of lime-water, given internally in doses of from five to ten ounces, according to the patient's age, and without any external treatment. It is only in cases where there exists abundant irritating secretion that he advocates sprinkling with carbonate of magnesia.

Ipswich.—Sir Henry Thompson's pamphlet on Cremation, published by King and Co., Cornhill, will give the information required.

The Indian Medical Service.

To the Editor of The Lancet.

Sir,—As a man of nine years' service, and having during that period served with both European and native infantry and cavalry, allow me to add a few remarks to the numerous letters which have appeared in your journal of late concerning the army medical service.

I have been waiting to see if anyone would call attention to the question, "purchase having been abolished in the combatant ranks," whether it would not have some influence in stopping a large source of supply of officers to our own ranks. Many men whose fathers are able to give them a few hundred pounds, perhaps sufficient to purchase a commission and pay for their outfits as ensigns, but who could not give them any further pecuniary assistance towards purchasing their steps &c.,—I have known many such men enter the medical ranks, their little fortune having gone in the expenses of their medical studies. Now it is very different. A boy only has to leave school, go to a crammer, and pass to get a commission, and enter the service as a sub-lieutenant about the age that he would be commencing his medical studies if he had taken that line; his small fortune still in hand as a nest-egg for exchanges &c. Now, Sir, at the present day would any young fellow of sense sink his money in a four years' course of study to enter the service as a surgeon, a sort of alien, belonging to no one, allowed to have his dinner on sufferance in the mess of the regiment with which he has the great honour of doing duty. After some twenty years' service, if in so-called medical charge of a regiment, he will be allowed as a great favour to pay heavy subscriptions and donations to band, mess, and other institutions during the five years he is attached to the regiment; but as for having any voice in the management of these things (except doing the butler's duty), why, in reality, he has less influence than the youngest boy sub-lieutenant. By-the-bye, I forgot to mention another privilege, that of wearing the Cardwell button and the facings of the regiment.

With regard to my Indian brethren, though, first, let me state that I myself have been very lucky, and got into a good regiment early in my service, therefore I am quite contented with my own lot; but I have seen so many men come out here, and get thoroughly disappointed and disgusted at once, and no wonder. They are led to expect that they will draw 450 r. per mensem directly they get charge of a regiment; whereas they can only draw 286 r., plus half the staff of the man for whom they officiate, which generally amounts to about 100 r., making a total of about 386 r. instead of 450 r. It is a very rare occurrence for a man to get a permanent appointment for some years, because appointments only become vacant by retirements or men getting higher appointments. At present the majority of men coming out here can only look forward to the officiating charge of some native infantry regiment, in which they can take no interest whatever either professionally or socially; for in most native infantry regiments, all, or nearly all, the officers are married, and their only object appears to be to pinch and screw to save rupees to enable them to get home. As for *esprit de corps*, there is no such thing in native infantry. Therefore if the "new doctor" happens to be a bachelor, the chances are that he will find himself the only dining member of a wretched mess. Then, again, extra appointments, such as charge of lock hospitals, divisional and brigade staff, &c., formerly always held by the Indian men, now are fast being given to the Queen's men, thereby losing to the Indian service in every station some 100 r. to 250 r. per mensem. I merely mention this fact to dissipate any idea any young fellow may have formed of coming into the service with the notion that he may get any of these little extra helps to his income. Not that we grudge the "Queen's men"; for, poor fellows, under the present undecided régime, their life must be more than a burden to them.

I noticed a letter in The Lancet some time ago. It spoke of medical officers' position and rank. Every man can make his own position individually, and may be the most popular officer in the regiment; but his department has no standing whatever, and is snubbed by every Jack in office, and much tact is required to keep out of quarrels in its behalf.

A surgeon is always expected (and quite right too) to address a field officer as major or colonel, as the case may be; but you never hear even the youngest joined cornet or sub-lieutenant address surgeon-majors, and sometimes even deputy surgeon-generals, as anything but plain "Smith," "Brown," &c. So much for rank. You really have none.

If a young fellow were to ask my advice as to whether he should come into the service as it now is, I should give him *Punch's* advice, "Don't."

I remain, Sir, yours truly,
Lahore, India, July, 1875. Lancer.

The Family of the late Mr. R. Thomas.

Mr. F. Wilkins (Burton-on-Trent) requests us to acknowledge the sum of 10*s.* from "A Friend" towards this Fund.

Subscriber.—1. There is no hard and fast line. Our correspondent should be guided by circumstances; but, as a general rule, we should be disposed to reply in the affirmative. The contrary course would have an ungracious appearance.—2. Through the Colonial Office.

Mackintosh's Swimming Collars.

To the Editor of The Lancet.

Sir,—Drowning accidents during bathing would be greatly diminished by the use of Mackintosh's swimming collars by ladies and children. These collars are approved by the Royal Humane Society, are not disagreeable to wear, and are effectual. Their cost is 3*s.* 6*d.*

Yours truly,
Rochester, August 21st, 1875. Fredk. J. Brown, M.D.

QUACK CIRCULARS.

A Father of a Family sends us a filthy circular by a quack, who styles himself "Dr. W. R. Godfrey, formerly of the Spermatorrhœa Hospital, New York," and pertinently asks whether the law cannot put a stop to the wholesale dissemination of such pernicious rubbish. As THE LANCET is read by a large number of lay readers, we would put such persons on their guard against this and other advertising charlatans. We would gladly see an enactment passed which would give the metropolitan magistrates power to deal summarily and mercilessly with these pests of modern society. Undoubtedly a large amount of mischief is caused by the wholesale publication of these circulars. The young and unwary are entrapped by the specious promises of cure held out into placing themselves under the care of ignorant men, whose only object is greed, and who fatten on their victims as long as they have money to pay for nostrums, which not unfrequently injure health to a serious degree. It is not unreasonable to ask that our large towns should be purged of this evil. The New World has given us an example of one way of dealing with these gentry. At San Francisco a black list is published weekly, containing the name and address of every person who practises medicine without a qualification, and the plan has been successful in stamping out quackery in its various complexions. It is rather humiliating to think that an evil interdicted in California should be allowed to flourish without let or hindrance in London.

CASE OF PLACENTA PRÆVIA.

To the Editor of THE LANCET.

SIR,—Cases of placenta prævia are not so common in country practice but what it appears to me advisable to chronicle in your pages any case that may occur, with its treatment and result.

On July 31st I was desired late in the evening to visit the wife of a labourer (under the charge of a midwife), who was stated to be suffering from sharp uterine hæmorrhage. I went, found a woman about forty years of age, pregnant with her fourth child, wanting seven weeks of her full time, who was the subject of bleeding, which had occurred for the first time that day. She was in no pain, but the discharge came at frequent intervals. Upon examination, there was no dilatation of the os uteri, and I was unable to determine whether it was a case of accidental or unavoidable hæmorrhage which I had to deal with. So I prescribed rest in the recumbent position, cold, unstimulating food, and a mixture of ergot and opium. On the next day (Sunday) the amount of bleeding had not lessened, and then a mixture of alum, dilute sulphuric acid, and tincture of opium was ordered. These mitigated the symptoms; but early in the morning of Tuesday, the 4th, I received a message, saying the bleeding was considerably increased, and the worst results were feared. I arrived at the house at about 8.30 A.M., and noticed that there were slight pains going on. Upon instituting an examination I found the vagina so blocked up with clots that their removal was necessary before an accurate state of affairs could be determined on. The patient was gently lifted on to the floor (in order that the bed might not be made wet), and the clots carefully washed away by the aid of a Higginson's syringe. The os was found to be dilated to about the circumference of a shilling, and nothing but placenta could be felt. The vagina was then plugged with a pocket-handkerchief, and soon after the pains became much more severe, and the bleeding proportionately increased at time of pain, escaping from the vagina pretty freely by the sides of the plug. In about three-quarters of an hour I removed the plug, and found the os dilated to an extent somewhat larger than a crown-piece. I then ran my index-finger round the inside of the uterus to separate the placenta as far as I could, and gave a dose of ergot. This operation diminished the bleeding. The pains increasing in violence, and the dilatation of the os continuing, I was shortly after able to feel the bag of waters round the edge of the placenta. I then guided the stilette of a male catheter up to and ruptured them. This proceeding entirely stopped the bleeding. Soon afterwards I felt a foot; as the legs descended they seemed surrounded by placenta, and, having drawn them down, soon was able to complete delivery, the after-birth coming away the same instant the child was born.

The woman made a good recovery, and felt neither faint nor exhausted during her anxious time. Yours &c.,

The Elms, Newbury, August, 1875. F. E. RYOTT, M.D., F.R.C.S.

Radius.—1. No, not necessarily.—2. We must refer our correspondent to Dr. Williams, of the Privy Council Office, or any skilled veterinary surgeon.

THE DEATH UNDER CHLOROFORM AT QUARRY BANK.

THE letter of *Mr. James Bradley* shall be published in our next issue.

AN ILLEGAL PRACTITIONER.

To the Editor of THE LANCET.

SIR,—In reference to the report of the above case in the daily papers on Saturday last, I think it is only right on my part to correct the wrong impression the report conveys to the general public and medical world.

Mr. Bridge, in passing sentence, stated that I came to Kensington, put up a brass-plate, and acted as a doctor. The facts of the case are as follows: I put my name up for the benefit of the different people residing in my house from time to time, and had no reference whatever to any medical practice. After being assistant to Dr. Leslie for more than a year at Westminster, I came to Kensington. He, still retaining me as his assistant, starts a provident dispensary at my house, which I managed, he and another medical man attending so many days a week. This is carried on till the end of last year, and did not cease a year ago, as stated in evidence. They then take their names down, and leave me for private reasons. I at once have the rules painted off the surgery door, and close the dispensary; but, being left with a number of patients on my hands, find it difficult to terminate our arrangement suddenly. Having had a private arrangement with Dr. Leslie, I considered I could continue to use his name, as I had been in the habit of doing, until I got qualified, or found some one else to take his place.

I also wish to state that the evening before my case was heard I was requested by Dr. Leslie to take charge of his practice at Westminster.

Hoping you will insert this explanation, as it is the only means I have of justifying myself, I am, Sir, yours obediently,

Allen-terrace, Kensington, Aug. 22nd, 1875. W. CAMLEY SMITH.

REGISTRATION OF DEATHS.

Potestas.—We should be glad to learn the true answer to our correspondent's question. Could not he ascertain it by inquiry? Registrars are much too easy in taking certificates from unqualified practitioners; but we are not prepared to charge them with registering deaths without something purporting to be a medical certificate or authority from a coroner.

ORIGIN OF THE PRESENT OUTBREAK OF CHOLERA IN SYRIA, AND ITS HISTORY UP TO THE PRESENT.

To the Editor of THE LANCET.

SIR,—The present epidemic of cholera originated in a manner so different from the previous outbreaks that an account of its origin will always be a part of the natural history of the disease.

Near the close of the past year, or the beginning of the present, a detachment of 400 or 500 Albanian recruits was brought into camp at Hamath. As Turkish recruits are apt to be, they were in a bad sanitary condition at the time of their arrival; but nothing of note occurred in their hospital until the 22nd of March, when a case of cholera appeared. It was rapidly followed by fifteen others among the soldiers, and, of the sixteen attacked, fifteen died. The disease then spread to the town, and prevailed with an average degree of severity, and still continues, after nearly four and a half months, with little abatement.

Hamath is a city of 30,000 to 40,000 inhabitants, mostly Moslems. It is situated on both banks of the Orontes, the most considerable river of Syria. The city is built on the meadows by the river's bank, and is at all times unhealthy during the hot season. The principal diseases at that time are diarrhœa, dysentery, cholera morbus, and various fevers, continued and intermittent. The streets, as in all Oriental towns, are the receptacles of garbage, and reek with the foul odours of the surface drains and heaps of filth. The damp exhalations of the soil and the mist arising from the river furnish the most suitable aid for the development of the diseases which are generated or aggravated by the above-mentioned causes, forcibly calling to mind the original focus of the cholera in the tropical regions of India. If to these circumstances be added the extreme abundance and cheapness of fruit and green vegetables, and the fact that many of the people live almost wholly upon them during the summer months, and prefer them in an unripe state, or from poverty not unfrequently consume them in such a state of decomposition as to be unfit for food, the mind will be prepared to recognise the possibility of the generation of a disease, which has not yet been proved to be the result of a materies morbi incapable of fresh production under the operation of suitable causes.

During the month of April, Dr. Pestallozza, the physician of the quarantine department in Beirût, visited Hamath, and pronounced the disease to be genuine Asiatic cholera. At the time of its appearance there was no epidemic prevailing in either Europe, Western Asia, nor Africa. No traces of communication with India could be detected. There had been no cholera for a year at Mecca or Jeddah or in Egypt, nor has there since appeared a trace of the disease in those quarters. Persia is quite free from all taint, and there has been no outbreak in the northern provinces of the Turkish Empire. Under these circumstances, and unless further investigation shall show a distinct foreign origin, the disease in Hamath must be regarded as endemic at the outset.

Soon after the spread of the pestilence in Hamath, a detachment of troops from the garrison was sent to Damascus. The officers of this detachment deny the occurrence of any cases of cholera on the road or before leaving the barracks. There is reason, however, to believe that this testimony is false. Subsequent investigations, notwithstanding the efforts made to conceal the truth, made it probable that a number of soldiers died on the route. Cholera appeared in the intervening villages soon after, and about the middle of June the rumour of fatal cases in Damascus spread dismay through Syria, and the speedy confirmation of this lamentable news, by daily reports of the severity and prevalence of the epidemic, caused the people of the cities to flock to Lebanon and Anti-Lebanon, which have always heretofore proved a safe asylum from its ravages. Almost the whole Christian and Jewish population of Damascus and Beirût fled, and the overcrowded villages and hamlets, notwithstanding the fevers and dysenteries and other maladies engendered by the massing of so many people, ill-equipped for their sudden journey and long summer residence, still afforded a safe retreat. A few unfortunates, who had contracted the disease before leaving the infected region, died on the way or in the mountain villages; but in no case thus far has the disease spread above the level of the sea-coast or the interior plateaux of Coele Syria and Damascus. The air of the mountains seems in some way to counteract the influence of the poison, and it may be hoped that, as heretofore, the many thousands of refugees will find their refuge secure until the disease has disappeared from the places where it is now prevailing.

On the night of July 5th a woman from Damascus arrived by diligence in Beirût, and after two days died of cholera. No further cases appeared for a week, although a sudden impulse of violence seemed to be given to the usual summer complaints, and the remaining Christians and many Moslems hastened their exodus to the villages of Lebanon. From the 20th July cases more closely resembling the Asiatic cholera have multiplied until about the 28th, when they became more numerous and pronounced, and at the present date (August 3rd) the epidemic may be said to be fairly inaugurated. It is also prevailing in Antioch, Aleppo, Sughbeen (a village of Coele Syria), Hasbeiya, Tiberias, Safed, and many smaller towns and villages. It is to be feared that before this reaches you it will have escaped the boundaries of this province, and then no one can predict its future course.

No quarantine has been attempted between Damascus and Beirût, and the farcical operation of fumigating the daily diligence and its passengers has been the only attempt to ward off the advent of the disease. The mountaineers have gone to Damascus, and in some cases contracted the disease there, and perished after their return to their homes. There is no quarantine between the infected cities and the mountains, and it is said that none will be established.

As regards treatment, too little time has been given in Beirût for the trial of the various plans. The chloral injection (hypodermic) will be fairly tested.

In a future communication I hope to give you more details on the subject of the origin of the epidemic, and the statistics of its ravages in the various places where it prevails. Respectfully yours,

GEORGE E. VOST,

Beirût, August 3rd, 1875. Surgeon to St. John's Hospital, Beirût.

Ziemssen's Cyclopædia of the Practice of Medicine.

Many of the subscribers to this work are aware that the volumes of the German edition are not being issued in regular succession—some of those treating upon subjects of greatest interest having the precedence, although numbered to conform to the plan of the entire work. It has been concluded to follow the same course with this translation; and in compliance with the expressed wish of many subscribers, volume x., Schroeder's "Diseases of the Female Sexual Organs," is now published with copious illustrations. Volume iv. will follow on December 1st, and volume v. on March 1st, 1876. The publishers, Messrs. Sampson Low & Co., announce that rumours of an intended change in the plan of publication are entirely without foundation. This work will be obtainable only by subscription for the entire set of volumes. No single volume or series of volumes will in any case be sold. The Cyclopædia is now being published in the English, German, Dutch, Italian, and Russian languages.

Dr. H. D'O. Foote.—Very soon.

Case of the late Mr. P. C. Merryweather.

To the Editor of The Lancet.

Sir,—In forwarding to you a list of the donations we have received since you last published the contributions to this Fund, we feel it will be a subject of much satisfaction to those who have kindly aided in this matter to know that the amount raised has done great and permanent good. Besides supplying immediate wants, it has enabled Mrs. Merryweather to take a good house, where she is already prospering, and maintaining and providing for the education of her children. She is very grateful indeed to all who have so kindly extended the helping hand in the time of her great need.

The appeals in the medical journals have brought assistance even from distant Kurrachee.

We are, Sir, yours faithfully and obliged,
Charles J. Hare, M.D. Cantab., F.R.C.P.
W. A. Atwood, L.K.Q.C.P.

Uncongenial Callings.

The *Echo* a few days ago published a well-written article, entitled "How to Succeed." The reason why men fail in life, says our contemporary, is that they choose for themselves work for which they are not fit.

"The 'learned' professions are crowded with 'failures,' who would have been brilliant successes in other walks of life. Men who are no use at all at *nisi prius* would have been second Nelsons on the quarter-deck; surgeons to whom no patient will entrust his limbs might have earned martial reputations for themselves out of hostile armies; and many a clergyman who can neither keep his congregation awake nor his children decently clad, might have been a "warm" man if he had taken to business instead of theology. The misfortune is, however, that half the world flatters itself that it is, and prides itself upon being, something that, as a matter of fact, it is not."

Hypodermic Injections of Morphia in Acute Gonorrhœa.

Dr. Pietro Gamberini publishes, in a late number of *Giorn. Ital. delle Malat. Ven. et della Pelle*, the report of two cases in which subcutaneous injections of chlorhydrate of morphia (one grain to half a drachm of water for two injections) were highly useful in soothing the urgent symptoms of gonorrhœa—painful erections and micturition, intense burning pain in the urethra, &c.—when belladonna, hyoscyamus, chloral, and other remedies had all failed. The injections were made into the perineum, and near the sides of the urethra.

University College, London.

A discrepancy appeared in our columns last week regarding the introductory lecture to be delivered in the Faculty of Medicine, University College, this year. An advertisement erroneously states (although it was supplied to us officially) that it will be delivered on the 1st October by Dr. F. Roberts. On page 280, however, it is correctly given. The address will be delivered by Professor Corfield on the 4th October.

Mr. H. Wild.—1. Watson on Medicine.—2. The little manual mentioned is a reliable one as far as it goes.

Fractures of the Thigh.

To the Editor of The Lancet.

Sir,—I have read with much interest your report of the address of Prof. Spence, delivered at the late meeting of the British Medical Association in Edinburgh, and I beg that you will afford me a small space in your valuable journal for the following description of an apparatus I have lately had constructed for the purpose of overcoming, if not all, at least most of the difficulties connected with the treatment, as recommended by Prof. Spence and others, for fractures of the thigh.

My apparatus consists of an ordinary wooden long splint, provided with a movable foot-piece running in a guide, and worked by a screw. To the lower surface of this foot-piece is attached a V-shaped piece of brass, which receives the loop of adhesive plaster as used in most cases treated by weight and pulley. In the centre of the lower half of this brass piece, the extremity of a screw, twelve inches in length, revolves after passing through a female screw fastened to the lower extremity of the splint. By means of this screw the distance between the foot-piece and the upper extremity of the splint may be increased or diminished, the foot-piece being at the same time kept perpendicular. On the outer surface, and a short distance from the upper extremity of the splint, two buckles are fixed, which receive two leather straps, one passing in front, the other behind the patient's body, and connected with a broad and well-padded band fastened with buckles round the middle or upper part of the sound thigh. By these latter counter-extension is maintained.

The method of application is as easy as the apparatus is simple. Take a strip of adhesive plaster, two inches in breadth, and of sufficient length to extend along the inner and outer surfaces of the injured limb, as high as the seat of fracture, leaving a loop of from four to six inches in length beyond the sole of the foot. Having fastened this in position, lay the splint (well padded) along the outer surface of the limb in the ordinary way, and pass the loop over the foot-piece. Make a few turns with a broad flannel bandage round the upper portion of the splint and the abdomen; next fasten the broad band round the sound thigh, and carry the straps to the splint buckles, where they are to be fixed pretty tightly; then, having made sufficient extension by means of the screw, the operation is completed by making a few turns with an ordinary roller round the leg and splint just below the knee.

The advantages which I claim for the appliance are—1st. It will be found most efficient in extending the limb to and maintaining it at the proper length. 2nd. The patient's comfort will be greater with this than with any other appliance at present known. 3rd. The cost is not great, and it is very easily applied.

There is another matter of great importance in cases of fracture of the thigh. The beds now in use necessitate in a greater or less degree the moving of the patient, and until recently no method of overcoming this evil was known. Lately a bed has been introduced into the London Hospital, with a simple appliance for using the bed-pan, which is very efficient, comfortable for the patient, cleanly, gives the nurses less trouble than any other, and requires absolutely no moving of the patient.

I am, Sir, yours respectfully,
R. H. A. Hunter, M.R.C.S.

Malvern-road, Dalston, Aug. 10th, 1875.

Doctors and Druggists.

To the Editor of The Lancet.

Sir,—Attention has been recently directed in the columns of your journal, and elsewhere, to the subject of chemists employing legally qualified men to visit and prescribe on their behalf—a practice which I regret to say extensively prevails at this end of the town; and as an instance of the manner in which it works, it may not be uninteresting or unedifying to relate an experience of my own with one of these anomalous practitioners. The facts are as follows.

I was called to attend a gentleman, an old patient, who had been seized with apoplexy. On my arrival I found the gentleman in question, Mr. O'Donovan, who had also been sent for in the hurry and alarm occasioned by the occurrence. After a few remarks he left me, as he said, in charge of the case. Shortly after I quitted the house to get some remedies from my surgery, being absent about ten minutes. On my return I found that Mr. O'Donovan had sent a mixture, leeches, blister, enema with syringe, &c., also voluminous written directions to the wife and nurses, and, worst of all, a note, cunningly devised, to supplant me in my attendance on the case, to be forwarded to my house if approved by the wife of the patient. On ascertaining that her wishes were directly opposed to the spirit of the note, she only accepting the remedies believing that I had forwarded them, I addressed a remonstrance to him for such unprofessional conduct and ungentlemanly treatment. Neither explanation nor apology was tendered. On the contrary, I was treated by the chemist who employed Mr. O'Donovan—viz., Mr. Garman, of 278, Roman-road, Old Ford,—to an eulogium of his merits and high professional attainments, and was also grossly insulted for daring to call his conduct in question.

My object in bringing this matter before you is not one of professional pique, but simply to point out a result clearly attributable to the baneful practice of which this is a product. It appears to me that it would never have occurred between gentlemen settled in the same neighbourhood, and each enjoying a professional reputation; while it is extremely likely to occur when strangers are introduced and employed as the factotums of an ordinary chemist.

I have the whole correspondence in my possession, and should be happy to place it in your hands for whatever use you may think fit to make of it.

I am, Sir, your obedient servant,
Robt. Rugg, L.A.H. Lond.

Tredegar-road, Bow, Aug. 18th, 1875.

THE "UNION" PAMPHLET.

To the Editor of THE LANCET.

SIR,—I have to thank you for your notice of the above pamphlet. With reference to the distinctive titles for each rank of medical officer, I desire to say that the utmost confusion is caused by the present indefinite system. The title "surgeon" may be either a boy fresh from Netley, or a man of fifteen years' service. Twice, on two separate troopship voyages, I and with me all the medical officers were wrongly cabined, because it is impossible to tell by the Army List the standing of the surgeons ranking with captains. In the same way the title "surgeon-major" may mean two separate grades, each of different rank. Now, in civil practice it is of little importance what I am called, because I live amongst the same people for years—they know my standing and position; but in the service it is not so. Constant movings, and every year meeting new people, it is necessary to know a man's exact position, and this cannot be done with our irregular titles at present. I suggested the military titles, because they are definite, and cannot be mistaken; but it is quite unimportant what the titles are, provided they are distinct and definite, which they now are not. Nothing is so unpleasant as to have to explain to a Q.M.G. or other officer your exact standing, when by reference to an Army List all should be clear. The naval people, by abolishing the subaltern grade of surgeon, and establishing the "fleet surgeon" grade, have made their ranks quite definite. We need the same done for us. As we demand equality with the naval doctors in rank, Mr. Gathorne Hardy will, of course, abolish the subaltern grade for us in the army, and that will make things clearer as regards rank; but a new title is needed for surgeon-majors over twenty years' service.

I am, Sir, yours &c.,
India, July, 1875. THE WRITER OF THE "UNION" PAMPHLET.

WOOD *versus* MANCHESTER, SHEFFIELD AND LINCOLNSHIRE RAILWAY COMPANY.

Dr. Dacre Fox's letter arrived too late for insertion this week.

A Lecture
ON
SOFTENING OF THE BRAIN.

By J. HUGHLINGS JACKSON, M.D., F.R.C.P.,
PHYSICIAN TO THE LONDON HOSPITAL AND TO THE HOSPITAL FOR THE PARALYSED AND EPILEPTIC.

We very frequently hear the expression "softening of the brain." It is often used by educated patients; for many people who simply suffer slight and often but temporary nervous exhaustion think, always erroneously, that they have "softening," or are going to have it. It is really an expression of pathological application, but just as the symptomatic word "apoplexy" has come to have a pathological meaning (effusion of blood), so the pathological term "softening" has come—so, at least, it appears to me—to be used, even by some medical men, as a name for a certain rude clinical grouping of symptoms in cases in which there really is no softening. This use of the term is to be deprecated. Let me mention the symptoms of cases wrongly called "cases of softening." We see patients who have become excitable, irritable in temper, and desponding; they have found that their attention easily fails, and that they cannot do their accustomed work; they usually sleep badly; they have often what they call headache, but it is mostly not an ordinary headache, either in kind or in position; it is a feeling of pressure, or sometimes of burning, and its seat is the vertex or the back of the head; there is very often, indeed, a disagreeable feeling at the occiput and in the upper parts of the spine, more distressing than pain—an intolerable physical feeling; the queer feeling in the spine is often intermittent, and frequently comes on slowly with great depression of spirits. Altogether there is a strange mixture of "mental" and "physical" symptoms. Recognising the group of symptoms I have mentioned as a fair clinical entity deserving particularly careful study, I do not see the evidence for the diagnosis that softening of the brain is the pathological change causing them. Such cases are called by the laity nervous debility, and often by medical men hypochondriasis. The symptoms, I think, indicate nervous exhaustion, beginning often in the sympathetic nervous system, and secondarily affecting the nutrition of the highest centres in the brain. Of course this is only hypothetical, for there is no morbid anatomy of such cases. Everyone's conclusion as to their pathology must, therefore, be hypothetical. These symptoms are often produced by excesses, and especially by sexual excesses, and by "fast life" generally; they are sometimes suddenly developed by fright, and may be brought on by misery or by overwork, either of the mind or the body, especially when the work is done under responsibility. Of course they occur most often in persons who inherit a weak temperament, who bear trouble badly, who are easily excited and easily depressed. In some of the cases the patients get quite well by simple common-sense care, and the delusion that they have softening vanishes. In the graver, prolonged, and ingravescent cases, I should think there was no softening of the brain, but rather greater firmness of it; atrophy of nerve-cells and fibres, with increase of connective tissue; there is some atrophy of the brain. In saying this I am not making a very strong statement. We often see considerable atrophy of the brain at post-mortem examinations on those who have died of non-cerebral disease, and whose mental condition has attracted no attention. Atrophy of brain is normal in old people; it is often seen in middle-aged drunkards and even in comparatively young people who have been long bedridden by wasting diseases not primarily involving the nervous centres. I mention this, as you may think the statement that there is some atrophy of the brain an extravagant conclusion as to the state of things in a man whose symptoms are those of prolonged and severe hypochondriasis or nervous debility, or whatever the right name or label is.

Be sure there is no softening in these cases. Indeed, I do not see how the diagnosis that there is actual softening of the brain is in any case to be possibly arrived at, *unless the patient has certain local paralytic symptoms, as hemiplegia, or some other symptoms implying a local cerebral lesion, such as affection of speech*; or, again, unless there be signs of cerebral tumour (severe headache, urgent vomiting, and double optic neuritis), or evidence of injury to the head. For, so far as I know, cerebral softening is always local; I know nothing of general or universal softening of the brain. To be warranted in diagnosing softening, you must have symptoms which point to local disease. I do not say that local cerebral softening cannot exist without localising symptoms. I only say that in their absence you are not warranted in diagnosing its existence. We know that large parts of the brain may be destroyed without any marked local symptoms resulting; these parts may be destroyed by the process of softening without causing marked local symptoms. But in these cases the softening is mostly about tumours or other kinds of adventitious products. It is, however, almost an abuse of language to speak of these as cases of softening. The softening is, I suppose, a result of encephalitis about the tumour. We shall not refer to these cases again. For all practical purposes they belong to a distinct category. The cases which deserve to be called cases of softening are cases in which there is blocking up of cerebral arteries, or, which is infinitely rarer, of cerebral veins. Of these only shall I speak.

It is from the distribution of arteries, it is "for arterial reasons" so to speak, that there are localising symptoms in softening. The highest part of the motor tract (corpus striatum) and adjacent convolutions are usually the parts of the brain damaged or most damaged in softening, or simply the parts of the brain which often undergo softening. And this is because the artery which supplies these parts is an artery—the middle cerebral—which often gets blocked up, for reasons we shall afterwards state. Hence hemiplegia and affections of speech are the symptoms to be most trusted in the diagnosis of cerebral softening, for they are the symptoms producible by disease of the parts mentioned as being supplied by an artery which often gets blocked up. Curiously, however, unless there be valvular disease of the heart to, as it were, insist on softening by the process of embolism, cerebral softening is frequently not diagnosed in cases of hemiplegia and affection of speech when it often exists. Suppose that perfect hemiplegia comes on in a quarter of an hour without loss of consciousness in a patient past middle age, who has not renal disease, we are practically certain of local cerebral softening. There is in these cases softening by thrombosis—a commoner cause of local softening than embolism. Thus we see that the word "softening" is used by some for cases of nervous exhaustion and cerebral atrophy where there is not that pathological change, and, strangely, those who so use it very often do not diagnose softening in the really simple cases of hemiplegia coming on without loss of consciousness where it does exist. Sometimes, indeed, when the diagnosis is made that hemiplegia has been caused by embolism, because the patient is young and has valvular disease of the heart. There seems to be no clear notion in the mind of the diagnoser that he has before him a case of softening. There are two reasons for these mistakes. First, hemiplegia is too often attributed as a matter of course to cerebral hæmorrhage, and softening is not thought of. This is, I think, because clot is oftener seen at post-mortem examinations in cases of hemiplegia, as it is a more speedily fatal lesion. We have more autopsies on patients who die from cerebral hæmorrhage, because they die sooner, and therefore under our care. Nevertheless, hemiplegia, *coming on without loss of consciousness*, is mostly caused by softening. I except cases of chronic renal disease, for hemiplegia in these cases, as a matter of fact, nearly always depends on effusion of blood, whether there be loss of consciousness at the onset of the paralysis or not. A second reason for the mistake in diagnosis is that there is a widespread impression that general mental symptoms *must* exist if there be "softening." I shall devote a great part of this lecture to show that this is an error, or, at any rate, it is an error to suppose that softening of the brain *necessarily* causes *general* mental symptoms *directly*. Observe, I say directly, because I shall show that softening may be preceded by general mental symptoms, and may be followed by general mental symptoms. But in neither case do these symptoms depend directly on that softening. Observe, too, that I speak of *general* mental symptoms. I admit that softening directly causes special mental symptoms—loss of speech, for example. I deny that it directly causes general mental symptoms, although I admit, as I have said, that it may be preceded and followed by them. It is practically convenient to speak first of *special* mental symptoms *directly* resulting from softening; then of general mental symptoms following it. Although out of chronological order, it is more methodical to consider the mental degradation which may precede an attack of softening after speaking further of arterial changes.

Certainly there is not necessarily any direct connexion betwixt cerebral softening and *general* mental symptoms. There need be no such symptoms at the onset. The typical case is that of the middle-aged man who, having gone to bed feeling well bodily and mentally, finds out when he gets up in the morning that he cannot use his left side, but who is as clear in mind as usual; yet that man has local softening, or rather thrombosis of an atheromatous artery supplying a part of the motor tract, which will therefore speedily soften. We are obliged to make some kind of arbitrary limit. We speak of cases commonly met with. But, as I shall tell you, later there may be deep coma from blocking of the trunk of the middle cerebral artery—coma as deep as that producible by large cerebral hæmorrhage. A patient may have, however, special mental symptoms, without any insensibility, at the onset of softening, and as a direct result of it. Such cases I now consider.

Special mental symptoms directly resulting from softening.—The parts of the brain which most frequently soften are, as I have just said, the highest divisions of the motor tract; most often the corpus striatum and adjacent convolutions—that is, in other words, the parts supplied by the middle cerebral artery. If a large part supplied by the right middle cerebral artery be softened, there need, after the shock of the onset, be no obvious mental symptom of any kind. If a branch of the *left* middle cerebral artery be blocked there is a mental symptom, but then it is not a general one, but an exceedingly special one—viz., affection of speech (aphasia). Affection of speech *is* a mental symptom. A person who has lost speech has lost a part of his mind. Indeed, if the *trunk* of the middle cerebral artery be blocked there is very extensive softening, and a state very like imbecility as well as loss of speech; the patient's power of expression in all ways, and even the exhibition of states of feeling by smiling, &c., may be gone. Even then the symptom is a special one—loss of language or loss of speech.*

General mental symptoms may follow local softening. We will for convenience speak separately of those following in a few days (these are usually temporary), and then of those following weeks or months after; these are often permanent. Remember the simple case we took for purpose of illustration. A patient, about fifty, has become hemiplegic without loss of consciousness. This is the symptomatic statement; the pathological statement is that he has local cerebral softening.

General mental symptoms following a few hours or a few days after local softening.—After a short time the hemiplegic patient may begin to "wander," although at first, and usually all through his illness, he can pull himself together, clearing his mind of his fancies, and can reply to ordinary questions correctly. The mental symptoms are of a general character. There is not a loss of one faculty in particular, but a reduction of the whole mind to a more automatic condition. The patient "wanders" about his business, about the persons or places to which he is most accustomed (which are most automatic to him). He imagines that he is doing his work, and he may take strangers for those persons to whom he is most accustomed. I repeat there is not here loss of any one faculty, there is no special mental symptom. The patient is reduced to a more automatic condition of mind. There is Dissolution, using this term as the opposite of Evolution. Then, of course, much depends on the kind of brain the patient had before his illness. Old drunkards will have more absurd delusions, illusions, and hallucinations than persons who have not abused their nervous systems. My own belief is that this state results simply because the hemiplegic patient's brain power is slightly reduced in a universally lowered bodily condition, and that it is not caused by the very local disease of his brain. A local softening, practically an absence of brain (circumscribed destruction, could not possibly cause such *active* mental symptoms as we have mentioned. These symptoms are, in my opinion, ofen owing to debility. Let me explain how I think *debility* produces *active* symptoms. Explanation is required, as the expression seems paradoxical, and the expression "debility" wants definition. Probably the hemiplegic patient has, for theoretical reasons, been put on a spare diet, a diet next to nothing, although the very local damage in his brain has not seriously affected his digestive organs—not obviously affected them at all. The palsy has alarmed and depressed him, and he has not in consequence slept, or has not slept well. Very likely he has had a strong purgative, and perhaps blisters to the back of his neck. These mental symptoms are often due in great part to want of food. Very likely the poor fellow may have every day for years eaten and drunk far too much. Some people eat little during the day, and then "stun" themselves at dinner. If such a man be taken hemiplegic just before his dinner hour he would feel the want of food in the night. We should be cautious how we begin to change a man's habits, even bad habits, very soon after an attack of hemiplegia. If we do not keep up his arterial tension the parts of his brain *the furthest from his heart* will not get plenty of blood. The parts geographically furthest from the heart are the most intellectual; he may therefore become delirious if his arterial tension be much lowered. When I have spoken more about arterial changes, you will see that the brain of a man who suffers softening is often one of which the apparatus for nutritive supply has long been getting slowly defective. He is usually past middle age. There is arterial degeneration, and thus the circulation of distant parts will fail very easily. So far, we have concluded that there is defective blood-supply, and corresponding defect of action of the highest, that is of the most intellectual nervous arrangements. But obviously this negative condition could not account for *active* mental symptoms. Before I speak of the manner in which I believe the active symptoms to result let me widen the field of observation.

I would earnestly beg you to bear in mind that I declare that such mental symptoms are not characteristic of cerebral softening; they are just as likely to occur with hemiplegia from clot as with hemiplegia from softening; they cannot be due directly to either; they cannot, as I have said, be due to a circumscribed "destroying lesion" of any kind. But we can go far beyond this statement—we can say that these symptoms are rarely dependent on *primary* disease of the brain of any kind. In general physicians' practice very active mental symptoms (delirium) are rarely even associated with primary disease of the brain of any sort. Of necessity they imply something wrong in the brain, but the brain is suffering secondarily, "functionally," as the popular and inexact expression is. Such symptoms are common in the medical wards of a hospital. The patients in whom they occur are those whose primary ailment is not a cerebral one; they occur in phthisis, in chronic Bright's disease, in pneumonia, in erysipelas, and in pyæmia—in some cases of these diseases, I mean. As a rule, the more acute the disease, and therefore the more rapidly the brain suffers secondarily, the more active, the more uproarious and constant, the mental symptoms. They occur without a very high temperature oftener than with one. The temperature is often normal. Now we come to the explanation.

Such mental symptoms are on an utterly different platform from all other kinds of nervous symptoms. Remark, they are positive, or, as I said, active symptoms. Negative mental symptoms, such as loss of speech, imbecility, defect or loss of consciousness, are often owing *directly* to disease of the brain, but the most extravagant and most changing positive mental symptoms must in all cases, even where there *is* disease of the brain, be due to the action of parts of the brain which are *not* the seat of a lesion which produces *loss* of function. They are due to the action of parts which, except for over-excitement, are healthy. I am fully convinced that in all cases, from the insanity of slightest delirium to insanity ordinarily so-called, there is, as Dr. Monro says (in accordance with a principle many years ago formulated by Laycock), a negative and a positive condition. There is loss or defect in the highest faculties along with exaltation of those lower and more automatic. It is even so in health; automatic mental action goes on during sleep or reverie. But we shall keep to actually morbid conditions. I wish to impress on you that it is the negative element only which is the *direct* result of disease. Now mark, the delirious patient is symptomatically in a double condition. The negative element is defect or loss of consciousness. Unfortunately such an expression often rouses thoughts about coma; but be sure that there are all degrees, from the slightest and most transient confusion of mind (defect of consciousness) to deepest coma. Now, the defect of consciousness is the condition produced directly by loss of arterial tension leading to failure of the highest centres—those most distant from the centre of the circulation. With regard to the causation of the positive symptoms (the delirious ravings &c.), we may apply the principle Anstie stated when he said "that the apparent exaltation of faculties is due to removal of controlling influences," or, as Thompson Dickson said of delirium and mania, that "they result from loss of control," or as Rutherford says,* "to diminution of inhibitory power." When a man is delirious his negative state is, I repeat, that his highest nervous arrangements in the cerebrum, the substrata of consciousness, are more or less put out of use; he has defect of consciousness. In any general lowering of health the very highest nervous arrangements are the first to fail. (Principle of Dissolution.) The positive or active symptoms, the illusions, delusions, and grotesque actions, are owing to the action of the lower nervous arrangements, which, except for over-excitement *permitted* by the loss of control, are healthy. (Principle of Loss of Control.)

---

* I must insist that loss of speech is a mental symptom. For we speak not only to tell other people what we think, but to tell ourselves what we think; rather a proposition is the ending of a mental operation, and often the beginning of another. The aphasic can still think in some fashion; he remains able to do so, I consider, because, although speechless, he is not wordless; he has remaining the automatic and unconscious use of words in the right undamaged cerebral hemisphere. I believe, too, that there is a similar duality of Perception, or, rather, that the process which ends in perception is double. This process is not affected in cases of aphasia. There is, I think, chiefly from disease of the right posterior lobe, a mental state which I call "Imperception," corresponding to Aphasia in the Word series. I do not discuss this symptom in the text, for, besides other and better reasons, the topics necessarily to be considered are numerous.

You may reply that the active mental symptoms may be attributed to active disease about the original lesion—about the softening or the clot. This is contrary to the evidence. It is a grave error in any case to put these symptoms down as a matter of course to meningitis, encephalitis, or to any kind of acute primary head affection. It is a deplorable error if it leads to severe purgation, to blistering the back of the neck, leeches, and low diet. The characteristic symptoms of encephalitis, meningitis, and acute brain disease generally are not mental, but physical. Thus, besides gross motor affections, convulsion, and paralysis, there are alterations of circulation, respiration, temperature, and constipation, vomiting, &c. Do not forget this seemingly paradoxical statement, that the trustworthy symptoms in the diagnosis of acute and primary disease of the organ of mind are physical, and that the untrustworthy symptoms for that diagnosis are mental.

General mental symptoms slowly developing weeks or months after an attack of softening.—These certainly follow at too great an interval to be erroneously attributed to the local damage which caused the hemiplegia. They often develop when the hemiplegia has become chronic. A general mental and bodily failure often follows a severe attack of hemiplegia, the result of local softening. It is not due to that softening nor to any extension of it; it is, I suppose, a result of secondary atrophy of the whole or of a large part of the hemisphere in which the local softening lies. But remark that widespread atrophy of a hemisphere follows on any large cerebral lesion, not on softening in particular; it follows clot, for example, and it may follow tumour, as is evident in some very long-standing cases. I say in some very long-standing cases, for, of course, in most cases of tumour, as we see them post mortem, from the added bulk and from œdema of the brain about the tumour, the convolutions are flattened and the brain looks bigger. Probably here there is concealed atrophy. In cases of autopsy in adults who have been hemiplegic from infancy, we may find, besides the local paralysing lesion, extreme wasting of one cerebral hemisphere. This is, I think, a consequence of the local damage which caused the hemiplegia. There was at first, I suppose, softening by thrombosis of a branch or of the trunk of the middle cerebral artery. This local softening is afterwards represented by a cyst. The atrophy is consecutive and secondary.

The mental symptoms following late (weeks or months) after an attack of hemiplegia are more slowly developed than those following immediately, hence they are very different. The deterioration shows itself both intellectually and emotionally. There begins to be loss of power of connected thought on difficult, novel, and complex subjects, or, speaking simply, the patient is soon confused; there is also peevishness and selfishness. Both these are highly characteristic of slow mental degradation. This is just what one would expect *a priori*. From a process so uniform as atrophy of the brain you would expect failure to begin slowly, and, on the Principle of Dissolution, that it would affect first the highest and most special of all faculties, or we may say those faculties last acquired both by the race and the individual. These faculties are power of abstract reasoning (intellectual) and sentiment of justice (emotional).* That these two faculties are the most special is seen by the fact that young children and savages have little or none of either. It is said that Australian savages have not even such abstract words as tree, red, justice, &c. Now, inferior people among the civilised are inferior because these faculties are little developed in them. I repeat, these are the two faculties developed latest; they fail first in cerebral disease where the whole brain is slowly implicated. So far for the principle of Dissolution, under which comes the negative condition. Next for the positive symptoms. The process of dissolution which directly causes the negative indirectly causes, or rather permits, the positive.

Patients with general cerebral deterioration, like persons naturally inferior, are easily excited; for by saying that they have defect in their highest processes, we say that they have defect in their controlling or inhibiting processes. To be easily excited is to have little controlling or inhibitory power. Here again comes in the Principle of loss of Control. Every healthy man has all animal passions and instincts, but the properly organised man has them under control of well-developed higher faculties. Thus chastity is not the absence of sexual feeling, but the having it deep under the control of higher feelings. Here you see that the principle of the same explanation holds good as was given of the mental symptoms following soon after local softening. In the production of the class of symptoms just considered, the process of dissolution is very slow, and thus the control is slowly removed. The suddenness and rapidity with which control is removed is of vast importance; the more rapidly it is removed the more activity is there of the centres uncontrolled. Thus, in the epileptic maniac (the most furious of all maniacs) the control has been removed very suddenly and with great rapidity.

Defective sense of justice seems too fine a phrase for selfishness, peevishness, and greediness; but it is really a correct statement of them. The feeling of justice is regard for others. Of course the results of disease are as different as are the persons to whose brains disease comes. For example, inferior men who have little sense of justice while in health, are made very irritable by trifles and easily take offence. They would soon, even by a non-cerebral illness, display bad temper, greediness, &c. Then some men have a feeling of justice in excess: generosity is excess of justice; generosity is not simply an easy, soft, careless nature. Such men are less likely to become selfish and greedy when the brain begins to fail. They have a reserve of good faculty. Defective power of abstract reasoning also seems too fine a phrase for the confused mental state of many of our hemiplegic patients. But it is really a correct expression; I don't mean that they have difficulty in reasoning on abstruse subjects. What puzzles them is connected thought about things out of their routine, and which are not simple and actually before them. Persons of congenitally inferior minds are easily confused by anything complex, especially if it be novel.

So, then, when general mental symptoms follow weeks or months after local softening a sufficient explanation is given, not by the softening, which may not increase in extent as the symptoms develop, but by the slow consecutive atrophy.

To resume. Excluding softening about tumours and softening from gross causes similarly obvious, I know nothing of softening of the brain except that resulting from blocking of cerebral vessels. This, you will see, is saying in effect that softening of the brain is local; there is a softening of some part because a vessel supplying that part is blocked up. I have used in a former part of this lecture the expression "extension of softening." I wish to remark that, excluding softening about tumours, softening from injuries, &c., I know nothing of "extension of softening" except in the very simple sense of its resulting from new blockings up of arteries near those formerly blocked up.

---

* The Lancet, April 29th, 1871.

* See Herbert Spencer's Study of Sociology, chap. xv.

The softening I have to speak of is a partial necrosis of brain mostly in arterial districts. Hence the first and essential thing in the study of softening is the study of the process and results of blocking up of arteries. It is exceedingly important to realise that it *is* a question of *arteries.* See how it bears on hereditary transmission of disease. Hemiplegia from local softening occurring in a person whose family has been subject to nervous disorders is no evidence whatever to show an inheritance of nervous disease, for the simplest possible reason that hemiplegia so caused is not strictly of nervous origin. The same remark applies to hemiplegia from clot, and thus it applies to nearly all cases of hemiplegia, for this form of palsy arises in the vast majority of instances from bad cerebral arteries; they break or get blocked up. Hemiplegia is the common arterio-cerebral symptom partly because an embolus can more easily get into the middle cerebral artery for anatomical causes, and partly because this vessel lies more directly in the way of strain from the heart, and thus is the most diseased and the most easily ruptured. To show how very mechanical, so to speak, the reason is for the predominance of this arterio-cerebral symptom, I mention that Prevost and Cotard found that tobacco-seeds injected into a dog's carotid most often lodged in the animal's middle cerebral artery. In fact, I know of no evidence to prove that any form of hemiplegia is ever of direct nervous origin—i.e., that the pathological changes causing it *begin in nervous tissue.* Hence it is, I think, very inaccurate to speak of a patient who suffers epilepsy as having a *tendency* to nervous diseases because his father or mother had such symptoms as hemiplegia, loss of speech, softening of the brain, &c. Your notions on hereditary transmission of nervous diseases will be confused unless you bear in mind that nearly all "nervous diseases" are really instances in which the pathological changes begin in *non-nervous tissue.* Very many of them begin in the compound tissue (artery), and many of them in the simple tissue (connective). Besides symptoms of arterial origin there are nervous symptoms from intra-cranial tumours (including syphilitic growths), abscesses, hydatid cysts, &c. All these are pathologically extra-nervous. So, in inquiring for evidence as to hereditary tendencies in a patient who had any kind of nervous affection, you try to get evidence as to general states; for what you really want most to know is to what tissue-changes the patient's family is prone. You only inquire about nervous symptoms in other members of the patient's family (paralysis, &c.) as indirect evidence of this. You inquire, too, for rheumatism, gout, for facts as to renal disease, as well as ask if there be paralysis, insanity, &c. What you most wish to know is, what tendency there is to arterial (including cardiac) changes. My own belief is, that in this direction of inquiry we shall find out the pathology of the neuroses. I do not believe that chorea and epilepsy are nervous diseases in the sense that the pathological changes *begin in* nervous tissue.

In all the cases I have mentioned so far nerve-tissue *suffers.* It is not primarily at fault. As to the neuroses, remark that according to most physicians their pathology is unknown. We cannot say, then, that they are hereditary as *nervous affections* simply because they pervade a family. Hemiplegia, apoplexy from cerebral hæmorrhage, softening, &c., may pervade a family, but this is not evidence that that family is predisposed to nervous disease, for the simple reason that all the three so-called *nervous* diseases mentioned are affairs of arteries, not a whit more significant than defect of sight from retinal hæmorrhage or epistaxis—arterial affairs too. In these cases it is more important to seek evidence of a tendency to arterial change than to note the occurrence of nervous disease or symptoms in the patient's blood-relations.

Mental symptoms preceding cerebral softening.—It is important for another reason to bear in mind that cerebral softening is a question of arteries; for, since local softening is due to blocking up of arteries, it is hard to see how such so-called causes of softening as anxiety and overwork can be said to produce it. Such causes may help to produce the clinical grouping of symptoms, often called softening, of which I spoke at the beginning of my lecture. Fright and anxiety—which latter is only fright spread out thin—are, indeed, potent causes, especially in predisposed persons, of severe, very distressing, and long-continued nervous symptoms, such as sluggishness of mind and body, failure of power of attention, incapacity for sustained exertion, &c.; but I do not see how they can produce that *local* pathological change which is properly called softening. I do not deny that hemiplegia from softening (thrombosis) is often said by patients and their friends to have been preceded by anxiety or overwork—"caused by" such things, they will affirm. I think the most reasonable explanation is that the brain has been slowly getting into a condition in which it is easily excited and easily overworked; for in many such cases (softening from thrombosis) there is widespread degeneration of the cerebral arteries, and thus a worse nutrition throughout the brain, before the actual softening of some part results because one of these bad arteries has become blocked up. In some cases before the hemiplegia, the patient had manifestly become, as he would say, although not in these words, incapable of connected thought on any unusual matter, forgetful of things slightly out of his routine duties, and we should learn from his friends that he had become irritable and selfish. What I told you on failure of the two highest faculties in consecutive atrophy of the brain applies here. As a rule, the failure of mental power before softening is much slighter, and occurs more slowly; it is often spoken of by the patient's friends as indifference to business, fidgetiness, and "alteration" of disposition. These symptoms are no doubt, in persons who have degenerated arteries, the result of an uniformly bad state of the vessels of the brain. This prior condition of ill nutrition does not, so far as I know, lead to *general* softening, however slight we may suppose that softening to be.

You will now see that the causes of softening of the brain, properly considered, lead you to consider the state of the arterial system—lead you beyond the nervous elements of the nervous system. I repeat that very few nervous diseases are directly of nervous origin. A great part of our knowledge of the pathology of cerebral softening is in the answer to the question, Why do arteries become diseased, and thus "blockable"? Obviously if the softening of the brain be very limited in extent, and the symptoms therefore slight and transitory, the consideration of the patient's general bodily state is the really urgent matter. It would be a very poor thing to dwell with exaggeration on the hemiplegia, and ignore the state of the patient's heart, arteries, &c. It would be a very unclinical mind which could feel comfortable about a patient who was very "degenerate" simply because he had speedily got rid of hemiplegia. Inquire into degenerations of all systems of tissues, and examine all important organs. Nor must you suppose that you are taking a broad view of a case if you dwell exclusively on important superficial matters—state of digestion, sleep, and occupation. You will have your patient's sympathies in making such investigation, for he can, or he supposes he can, follow your inquiries and understand their bearing. It is best to begin with the paralytic symptoms; then to consider the superficial, but very important, conditions; and, lastly, the deeper lying and most important evidence as to general pathological and pathogenetical states. The patient will wonder what you are at if, first of all, you examine his heart, urine, and arteries, when he comes to you because he cannot use his right arm and leg. Again, do not be illogical when the paralytic symptoms are slight and transitory. Suddenly occurring and transitory slight symptoms, such as affections of speech, unilateral numbness, may be owing to little foci of softening (or rather to thrombosis of small arteries, which in due time lead to local softening), just as much as permanent paralysis may be owing to extensive softening. Of course the slighter the symptoms the more need is there practically to consider many possibilities, for slight symptoms are not necessarily so easy of explanation as grave symptoms often are. After carefully considering all the causes I can think of, I feel warranted in attributing in many cases the slight and transitory nervous symptoms I have mentioned to local softening; for vessels of very small size may be blocked up as well as vessels of great size, and in correspondence there are foci of softening from the size of a pea upwards. Simple as this remark sounds, the principle deducible from it is not always borne in mind. Slight and transitory hemiplegia, which we are warranted in putting down to blocking up of very small arteries, is often hastily ascribed to general states of ill-health—for example, to affection of the liver, &c. In so explaining them you would have your patient's sympathies. He can, or thinks he can, frame some sort of conception of "local congestion," "disorder of the liver," "suppressed gout," "overwork," "anxiety," &c., as causing his slight localised nervous symptoms. At any rate these explanations or these phrases are familiar to him. I think that the existence of any of these states gives no explanation of local and suddenly occurring nervous symptoms. These "explanations" are superficial, not simple. If a man have atheromatous arteries (blockable arteries) of all sizes, why should not slight and transitory symptoms be owing to blocking of very small arteries? Observe, the question of first importance in diagnosis is not as to the slightness or transitoriness of a symptom, but as to its localness; a local symptom must imply a local lesion of some sort. One reason for the frequent denial that local lesions exist in cases of *transitory* paralysis is that it is not widely known that there is Compensation in nervous organs, so that paralysis will pass off when the damage causing it is not altogether repaired. Thus, we exclude such so-called general causes as I have mentioned, and go on to consider special causes. At the same time it is only an inference that such slight and transitory paralytic symptoms depend on small foci of softening; for there is no, or practically no, morbid anatomy of such slight symptoms.

REPORT OF A

CASE OF POPLITEAL ANEURISM CURED BY PRESSURE.

By STAFF-SURG. ALEX. TURNBULL, R.N., M.D.

(*Communicated by the* DIRECTOR-GENERAL OF THE MEDICAL DEPARTMENT OF THE NAVY.)

IT appears that the subject of this case (S. I——, aged thirty-five, master-at-arms), in the execution of his duty, parted two men who were fighting, and in the consequent struggle caught his right foot in a ring-bolt, and severely twisted the right leg and knee-joint. This occurred on the 10th of December, 1874. As head of the ship's police, his duties at this season were of a very responsible nature; and though he still felt the effects of the accident, ultimately becoming lame, with œdema of the leg and foot, he did not come under treatment until the nineteenth day after the accident—viz., on Dec. 29th.

The patient is a large-framed, muscular, obese man, six feet in height, a free but not dissipated liver, and a history devoid of syphilis or other degenerative disease.

Dec. 29th.—Having spent a night of great suffering, the patient applied for advice this morning, when an aneurism was discovered filling the right popliteal space, and there was marked œdema of the leg and foot. The aneurism measures—length, 4½ in.; semi-circumference at centre, 6½ in.; circumference of left knee, 15⅜ in.; right, 16⅝ in. The aneurism is posterior to the popliteal artery, and has a strong heaving pulsation. The contents of the sac are apparently still fluid, and the aneurismal bruit clearly audible. The posterior tibial and dorsal arteries of the right foot are hardly perceptible. No sign or symptom of arterial or cardiac disease exists elswhere; pulse quiet, equable, soft, 80. Strict rest in bed enjoined, and patient instructed in the use of Signorini's clamp tourniquet to slow the femoral circulation, and prepare for the future treatment by arrest of the circulation through the aneurism.

30th.—Patient slept well after the hypodermic injection of a quarter of a grain of morphia. Experiences great relief from the intermittent use of the clamp tourniquet. He was placed on an air-bed, and the tourniquet carefully employed to avoid local irritation; on its removal, the part was dusted with fuller's earth, a piece of spongio-piline being always applied over the sites of pressure.

31st.—Patient shows signs of suffering from the restraint and confinement, having been accustomed to an active life. Average local daily temperature 80°; daily range 2° to 4°. Aneurism remains as on admission; there is, however, little or no œdema of leg.—4 P.M.: Most acute pain across dorsum of foot, apparently due to pressure of tumour on peroneal nerve; pulsation in aneurism strong and full; measurements unchanged; right knee partially flexed. Intermittent pressure, to diminish force of circulation, still employed with caution; hypodermic injections of morphia when pain is severe.

Jan. 1st.—Slept well. Intermittent pressure as before; diet generous and unstimulating; no stimulants.

2nd.—Having had a Lister's tourniquet made on board, and the patient become more accustomed to the confinement and use of instruments, I determined to arrest the circulation through the aneurism by the alternate use of Signorini's and Lister's tourniquets, the precautions noted on the second day being most carefully attended to. In 1868 I succeeded in curing a smaller popliteal aneurism by this method in four hours and a half; the case had been previously under treatment for some time by modified pressure.—8 A.M.: Applied Signorini's clamp over femoral artery about an inch and a half below Poupart's ligament, and Lister's clamp over ordinary seat of ligature; at intervals of half an hour or less, if pain arose, the pressure was removed, the other tourniquet having previously been applied. By these means the patient was not needlessly distressed, nor was circulation through the popliteal artery allowed.—Noon: Removed tourniquets. As it had been impossible to give constant medical supervision, it was discovered that pulsation had not been entirely suspended during the four hours. Subsequent experience in this case demonstrated the necessity of screwing up these clamps from time to time, as the soft tissues give under the pressure, and pulsation will often return in the aneurism under the same application of the clamp, which at first, and for many minutes, completely arrested it.—2 P.M.: Under my own supervision the tourniquets were reapplied alternately for four hours and a half, and I then experienced the difficulty mentioned of completely arresting the circulation through the tumour. The patient suffered much from the pain in leg and foot previously noted, but comparatively little from the immediate pressure of the clamps. On removing instruments, the aneurism felt more solid and the pulsation feebler, less heaving and expansive.—12 P.M.: Acute pain in calf of leg and across dorsum of foot; no œdema; no diminished temperature; subcutaneous injection one-third of a grain of morphia.

3rd.—A restless night; broken sleep; appetite poor; tongue coated; pulse 72–80; marked change in aneurism; pulsation decidedly feebler; tumour firmer and more solid. Patient confirms this from local sensations, and is much satisfied, entering thoroughly into the plan of treatment, and submitting most patiently thereto.—1 P.M.: Acute pain across dorsum of foot; hypodermic injection; flannel bandage.—2 P.M.: Reapplied instruments, the pain being relieved; removed clamps after two and a half hours' application under my own supervision; still a difficulty in entirely suspending pulsation in tumour; no appreciable difference in circumference of knee-joint on removing pressure; pulsation more feeble; clot evidently forming.

4th.—Slept without anodyne; patient's appetite poor; tongue coated; pulse 80. It was intended to discontinue instruments for a day, but at noon the pain in foot became so severe they were applied to slow circulation, and were thus employed for three and a half hours, under which treatment the pain ceased.—10 P.M.: Pain of foot returned severely. Ordered half a grain of morphia as a subcutaneous injection, with friction to foot.

5th.—3 A.M.: Still suffering greatly; unable to sleep. Again applied modified pressure with relief to pain, though slight consequent œdema of limb; this treatment continued for eight hours. The aneurism is increasing in solidity; the patient is observed to flex the limb more and more daily. Circulation through aneurism arrested by forcible flexion or extension of knee-joint. Moderate flexion to be employed, and maintained by slipper secured to waistband. Some slight tenderness at sites of pressure, which of late has been very constantly applied.—10 P.M.: Morphia hypodermically.

6th.—Slept well; treated this day by moderate flexion only; no return of pain in foot. Appetite improved; patient in good spirits, becoming more accustomed to the confinement.

7th.—Slept well without an opiate; the condition of the tumour satisfactory; pulsation feeble; tumour more solid. Treatment this day: Moderate flexion and rest only.

8th.—Rest and moderate flexion.

9th.—Pulsation feeble and easily arrested by flexion.—9.30 A.M.: Forcible flexion attempted, but after an hour's treatment the aneurism was found to pulsate, and the patient requested the clamps might be substituted. Half a grain of acetate of morphia had been subcutaneously injected ere the treatment commenced.—10.30 A.M.: Applied clamps alternately, with a view to arrest circulation through the femoral artery, as on Jan. 2nd. Constant medical supervision could not be given, but the patient managed the instruments well, though not so as to arrest circulation entirely at all times. This treatment was continued for seven hours. On removing the tourniquets the pulsation in the aneurism was very feeble. The tumour had entirely lost the feeling of fluidity, and the sensation experienced might equally have arisen from any solid tumour situated over the popliteal artery. The aneurismal bruit, however, was still audible.

10th.—Passed a good night without opiate; moderate flexion maintained by slipper. There was some tenderness at sites of pressure. Moderate flexion alone employed this day.

11th.—Aneurismal bruit still audible. Treatment as yesterday to allow local effects of pressure to pass off.

12th.—6 A.M.: Applied Signorini's and Lister's clamps, as on the fifth day.—8 A.M.: Pulsation not entirely arrested; reapplied instruments, and under my own constant supervision and management thoroughly arrested the circulation through the artery until 3 P.M., when, on removing the tourniquets, no pulsation returned in the aneurism. Moderate flexion and perfect rest were maintained strictly for the next two days. During the prolonged arrest of circulation very little distress was experienced. The tourniquets were at first changed every thirty minutes, but later in the day every fifteen minutes. When not in use they were removed, and the compressed skin dusted with fuller's earth and exposed to the air. The patient could have continued the treatment if requisite, and made a good meal at the termination thereof. At noon the pulsation in the superior and inferior articular arteries around the knee-joint was well marked, and so much so was this the case in the popliteal space over the tumour that at first it was feared pulsation had returned in the aneurism. There was no resulting œdema of leg, or marked coldness. The flannel bandage, which had been constantly applied during the treatment, was continued, and the limb covered with a blanket, under which it gave a sensation of increased temperature, and perspiration ensued.

13th.—Slept soundly. "Feels as if he could get up and run." Condition of limb most satisfactory.

14th.—Removed slipper, and discontinued moderate flexion. Leg can only be partially extended.

16th.—Patient discovered standing on left leg, and kneeling on right knee, enjoying a "wash all over."

17th.—Allowed to sit in a Derby chair with foot rest; still unable to extend leg, owing to size of tumour, which now measures—length, 4 in.; breadth, by callipers, 2 in.

20th.—Moving about on crutches; leg slung by means of slipper and bandage passed over shoulders; still unable to extend leg; tumour solid, and diminishing in size.

23rd.—Detected a brawny induration of integument about 2 × 1½ in. in size, situated immediately below the internal tuberosity of tibia, and slightly overlapping the internal border of same bone. The indurated integument is divided into two parts by a well-marked sulcus, apparently in the line of the internal saphenous vein. There is no œdema of leg; the swelling is a little tender on pressure; there is no increased heat of part, but a vague feeling of fluctuation close to internal border of tibia. Patient's general health good; appetite good; sleep sound. Ordered to remain quiet.

25th.—Signs of suppuration more decided; no apparent connexion with consolidated aneurism. Opened abscess and evacuated an ounce or so of grumous fetid pus, deeply stained with blood; there was free arterial hæmorrhage from divided integument. The abscess was opened, and subsequently treated antiseptically by Lister's plan.

29th.—Since the abscess was opened there has been a slight sero-sanguinolent discharge when dressed, flowing most freely when pressure is made over the sulcus noted on 23rd. A probe was this day passed through incision upwards along this sulcus, or sinus, a distance of 3 in. It seems evidently the internal saphenous vein obliterated by thrombosis and subsequent suppuration.

30th.—Patient allowed to sit up in a chair with a foot-rest. Discharge from abscess almost *nil*. Continue antiseptic dressings.

Feb. 6th.—The abscess has ceased to discharge for four days. The induration of the integument is disappearing; the sulcus noted still apparent. The aneurismal clot has diminished considerably, and is now the size of a duck's egg. Extension of limb is nearly perfect. Patient moves about on crutches, and is commencing to put his foot to the ground.

Remarks.—In concluding the record of this case of treatment of aneurism by pressure, I would draw attention to the great advantage in such a method of qualified medical supervision being constantly at hand, and of taking every precaution to prevent the patient being distressed either locally or generally by the treatment.

In this case the treatment was suspended for two and on another occasion for three days, in order to let all uneasiness from pressure subside. Moderate flexion was certainly employed at those periods of rest, but more with a view to maintain perfect rest than to check the circulation; it caused no inconvenience to the patient.

Screw-pressure, unassisted by springs, requires most careful and constant watching, if the object be to stop the circulation. Pressure by weights or springs evidently must be superior to the means at my disposal.

At the date of these remarks (Feb. 10th, 1875) I am very sanguine that the patient may return to duty ere long, after being resurveyed by a medical board.

Zanzibar.

NOTE ON

THE TREATMENT OF SCARLET FEVER BY THE EXTERNAL APPLICATION OF COLD WATER.

WITH TWO CASES.

By JOHN EDWIN EDDISON, M.D.,
PHYSICIAN TO THE LEEDS INFIRMARY, THE FEVER HOSPITAL, ETC.

(The Cases reported by Dr. STEELL, *Resident Medical Officer at the Fever Hospital.)*

NOTWITHSTANDING all that has been written in support of the treatment of fever by the external application of cold, there can be little doubt that the value of this method, at any rate in the case of scarlet fever, is not yet fully appreciated by the profession generally. There is no novelty in the subject now, and no space need be occupied in referring to the practice and opinions of Currie in this country, or to the more recent publications of various physicians who, especially in Germany, have practised and strongly advocated this method of treatment.

The two cases reported in connexion with this paper are published, not because of any special feature about them, but particularly because they are ordinary cases, such as occur in every-day practice, and because they serve to show that this plan of treatment is as serviceable in such cases as it is in those special cases of unusually high temperature that have of late attracted so much attention. I am inclined to think that the published cases of "hyperpyrexia" successfully treated by cold have unfortunately led to the belief that the treatment may be very good in such special cases, but that it is not particularly useful in the ordinary cases that frequently come before every medical practitioner. The late Dr. Anstie, in particular, exerted himself to urge upon the profession the desirability, or rather the duty, of more generally adopting the method; but even his able advocacy has not been so successful as it deserved.

Scarlet fever seems, more than any other acute disease, to lend itself to this treatment. The patients, as a rule, are young, and therefore easily moved about, and the beneficial results are generally more rapid than in the case of many other diseases.

All sorts of objections have been, and still are, urged against the use of cold in scarlet fever. Danger is said to arise from "driving in the rash," from internal congestion, from the rapid loss of body temperature and consequent depression, and it is also said that the risk of renal mischief is thereby increased. If it were proved that the occurrence of nephritis is more frequent after treatment by cold it would be a very valid objection to the practice of it, and the real truth can only be learned by an examination of a large number of cases. From my own experience I am inclined to disbelieve that any harm results in this way. The fear of the occurrence of nephritis from this cause originates no doubt in the generally accepted opinion that the affection of the kidneys so commonly occurring after scarlet fever is due to "draughts," or "catching cold," or to leaving bed too soon. I think this opinion is not founded upon sufficiently good grounds, and that everyone in the habit of seeing cases of scarlet fever must often have seen nephritis beginning before as well as after the patient has left his bed, and as often in cases kept in warm stuffy rooms as in those in which fresh cool air has been freely admitted to the sick chamber. "Catching cold" is made to do duty as a cause of so many conditions for which we can find no better explanation, that it is adopted at once and without hesitation in order to account for any otherwise inexplicable phenomena. There appears, at any rate, to be no good ground for assuming that cold bathing increases the chance of an attack of nephritis, and in the two cases here reported the urine did not become albuminous after repeated bathing. Objections on the ground of the trouble and increased expense in nursing are scarcely worth consideration if it is true, as I believe it is, that this mode of treatment is better than any other. The difficulty is perhaps less in treating scarlet fever than in dealing with other cases because the patients are usually young and easily lifted in in and out of the bath, but when from the weight of the patient or the weakness of the attendants it is impossible to use the bath, the patient may easily be packed in wet sheets, with or without pieces of ice placed here and there, or india-rubber bags or large bottles filled with ice may be placed round the patient. The bath gives better results than any other plan when it can be thoroughly carried out, and the most satisfactory way is to begin with the bath at 98° or 100°, and cool down gradually to about 70°. It is of course better that the temperature of the patient and of the water should be frequently taken, but the hand is generally a good enough guide as to the water, and the appearance of the patient always indicates the improvement in his condition. This is well illustrated in the case of S. F—— (aged eight), near the end of the fifth day. The little patient was then drowsy and delirious, the temperature being 104°, and three-quarters of an hour in a bath, beginning at 90° and cooled down to 68°, resulted in the cessation of delirium and drowsiness, and a reduction of the temperature (in axilla) to 95°. In the case of M. A. S—— (aged four), a similar bath for one hour reduced the temperature from 105·3° to 95·6°. There was no dangerous depression or bad symptom whatever from this low temperature. In scarlet fever, as in other allied disease, the cardiac impulse and the character of the heart sounds are safer guides as to the condition of the heart and circulation than is the pulse at the wrist, the latter being often very deceptive.

In the case of S. F——, it will be noticed that the temperature rose again and again after removal from the bath, the rise beginning sometimes immediately, at others after an hour or less. This rapid rise is usual in severe cases, and the benefit derived seems always to be in proportion to the length of time during which the high temperature is warded off. It is worth consideration whether it will not ultimately turn out to be a better plan to keep the patient in the bath for many hours, even for a day or longer if necessary, cooling the water very gradually down, and maintaining it at whatever degree is found to keep the patient's temperature nearest to a healthy point. In the treatment of diseases or injuries of the skin, no evil, but, on the contrary, great good results from much more prolonged baths; and it seems far more reasonable to prolong the period of immersion than to take the patient out and allow the temperature to rise, to be again and again reduced in the same way. I am well aware that unpractised writers like myself often seem to be regardless of the time of their professional brethren, but I trust that the above remarks will not be considered too long nor be found altogether useless. The notes of the cases are, I think, sufficiently detailed and clear to need no further explanation. The first case was one of more than usual severity; and the second, though not quite so serious, was yet by no means a mild case, as a temperature of over 105° and a pulse of extreme rapidity indicate.

I should add that all the baths were begun at a comfortably warm temperature—between 90° and 100°,—and cooled down slowly to about 70°, or sometimes a few degrees below that.

(To be concluded.)

A NEW MODE OF TREATING CERTAIN TUMOURS OF THE LYMPHATIC GLANDS.

BY S. MESSENGER BRADLEY, F.R.C.S.

AT the recent Edinburgh meeting of the British Medical Association a paper of mine was read in which I advocated the subcutaneous injection of iodine in certain cases of lymphatic tumours, and as I have since then employed this method in several fresh cases I have thought that a brief account of the mode of procedure might prove interesting. It must be premised that I do not speak of lymphatic tumours generally, but of certain kinds only; thus I do not refer to syphilitic or carcinomatous affections, or to the infectious or soft form of lymphomata, but confine my attention to three groups. First, true hypertrophies of the lymphatic glands, with or without a strumous diathesis; second, strumous hypertrophies—i.e., cases of cellular hyperplasia *plus* caseous deposit; and, third, hard non-infectious lymphomata, which present many points of resemblance to the first groups, and, indeed, are often only distinguishable in being multiple.

Now, there is perhaps nothing more common than to paint iodine over all the above-mentioned tumours unless it be the disappointment which results. This, at least, is my experience, the result apparently being the same whether the iodine is painted indiscriminately over the whole gland or whether it is applied, according to Furneaux Jordan's advice, over the contiguous lymphatics rather than over the gland itself; and yet all that seems to stand between this treatment and success is the thin skin which intervenes between the gland and the pigment.

The first case in which I injected iodine into a tumour did not appear very promising, though it proved perfectly successful. It was an encapsulated tumour, about the size of a large walnut, situated beneath the lower jaw, which I should have removed with a scalpel, had I not once had some unpleasant hæmorrhage in a precisely similar case; and as the patient in the present instance lived at some distance, I resolved to try to procure absorption before resorting to extirpation. *The tumour almost disappeared with the first injection*, and after one more it could not be at all detected. I was pleased with the result, because it appeared to me to be so desirable to adopt such a plan at one's consulting-rooms, and in the out-patient room of the hospital, instead of using the knife, which is always more or less terrible to the patient, and which is sometimes, in the most careful hands, followed by unfortunate results. Since the case I mention I have been in almost the daily habit of employing iodine in this manner, and I think I may venture to affirm that, by properly selecting cases, a successful result may be assured, while there is no doubt that an indiscriminate use of the remedy will be productive of disappointment. The best cases are those where a single cervical gland is hypertrophied in an otherwise healthy (adult) subject. Five or six injections of the simple tincture of iodine (five to ten minims at a time, according to the size of the tumour), at intervals of about four days, generally effect a cure. The earlier stages of strumous hypertrophies are also very successfully treated by this method, as are the small hard multiple lymphomata; but in the later stages of strumous disease of the cervical glands, where the tumour is broken down into a mass of caseous matter, and the neighbouring skin is blue and undermined, no good results follow from the injection of iodine; and, indeed, these cases are best treated by a careful excision of the disorganised and degenerated glands. I have also recently employed iodine injections in a large and hard fibroid bronchocele, which had been treated unsuccessfully by the internal administration of the drug. The tumour was not only inconvenient from its size, but had almost destroyed the voice, and so pressed on the trachea as to deflect it to the right side of the neck. The case is still under treatment, but the first two injections of ten minims of iodine were followed by the diminution of an inch in the girth of the neck. By parity of reasoning we may expect this method to prove serviceable in uterine myomata and allied growths, but it is to its value as a remedial agent in cases of lymphatic enlargement of the cervical glands that I especially wish to call attention, and I may briefly summarise my results on this head by a tabular statement:—

1. *Cases of cervical tumours to be treated by injection of iodine.*
   - *a.* True hypertrophies of the lymphatic glands without strumous admixture.
   - *b.* Strumous hypertrophies before breaking down.
   - *c.* Hard lymphomata.
   - *d.* Encapsulated cervical tumours, as a tentative operation.
2. *Cases of cervical tumours to be treated by incision.*
   - *a.* Strumous glands which have broken down into pus, with or without previous treatment by injection.
3. *Cases of cervical tumours to be treated by excision.*
   - *a.* Strumous glands infiltrated with caseous matter, which may be rocked to and fro upon a base of degenerated cellular tissue, with a margin of blue undermined integument.
   - *b.* Encapsulated tumours which have resisted the treatment by injection.

Manchester.

OXALURIA.

BY JAMES REOCH, M.A., M.B.

(*Concluded from page* 310.)

THESE earthy salts are of three chief kinds—carbonates, phosphates, and oxalates. The carbonates may be dismissed, because, though common in decomposing urine, they do not appear in ordinary urine when voided. The phosphates also, though always present, never seem to be in sufficient quantity to exhibit insolubility in alcohol. If the average quantity of lime be 3½ grs. in 52 oz. of urine, it will be found on trial that two or three times this amount, in the state of acid phosphate, will give only a faint turbidity when alcohol is added to its watery solution. We are therefore thrown back on the oxalates as the chief source, if not of the white precipitate which immediately appears when alcohol is added to urine, at least of the permanent turbidity which results on shaking the mixture. But this is never a good way of obtaining oxalates; for, being thrown down quickly, they are in the form of granules, and never assume the envelope shape, however long they are afterwards allowed to stand. The alcohol ought always to be added gently to the top of the urine, and the whole allowed to stand for twenty-four hours. If the urine possesses oxalates in abundance they will of course be thrown down without the alcohol, and if it has none at all the alcohol cannot make any appear; but the vast majority of urines are placed between these extremes, and therefore give few or no oxalates unless alcohol be added. It is easily calculated that an ordinary microscopical preparation covers 10,000 times the surface which is taken in at one field of view under a power of 300 diameters; but, since it is rapidly passed over, suppose it to be only 100 times the size, and the effect of alcohol in precipitating oxalates will be appreciated when it is said that, of 41 urines examined, there was an average of several oxalates in each field of view in nearly every one to which alcohol was added, whereas without it there was often scarcely an oxalate to be found in a whole preparation. To be more particular: from 10 cc. to 15 cc. of 36 specimens of urine from the same person, taken indiscriminately at three or four different periods of the day, were put into some test-tubes; half of them had 3 cc. rectified spirit added to them gently; the next day the excess of urine was poured off, and the few drops at the bottom examined microscopically. Where oxalates were seen, their average size and number were noted and reduced to the uniform standard of $\frac{1}{3000}$ in. in the side. The following table expresses the comparative results obtained:—

	No spirit.		Spirit.
No. of urines examined	36	...	36
No. of times oxalates were found in twenty-four hours	30	...	35
No. of times one average oxalate of $\frac{1}{3000}$ in. was found in each field of view	16	...	33
No. of times ten such oxalates were found in each field of view	1	...	15

This table indicates the effect of adding alcohol to urine, and it may be here observed that this explains a well-known fact which has not been hitherto fully accounted for. Every surgeon knows the evil effect of alcohol in cases of stricture, but the cause is not so clear. Congestion of the mucous membrane is an unsatisfactory because merely theoretical explanation, but the greater tendency to precipitation of oxalates explains matters perfectly. If a crystal of uric acid or triple phosphate be gently pressed under the microscope it will be reduced to powder, but an equal or even greater pressure has no effect on oxalates; they are therefore comparatively hard, and as they present six solid sharp angles, each of which is finer than the sharpest needle, they must inevitably tend to irritate the already diseased bladder and urethra. But, however this may be, the fact remains that addition of alcohol to urine in a gentle manner causes increased precipitation of oxalate of lime, and this may serve to throw some doubt on the alleged fact that carbonated drinks increase the amount of oxalates. It is natural to suppose, seeing the almost universal prevalence of oxalic acid in the vegetable kingdom, and its simple relation to CO_2, that it could easily be formed from CO_2; but this is not the case, and the facts above related show that it is to the alcohol, and not to the CO_2, we must look for an explanation of the oxalates; not that the alcohol forms the oxalates in any way, but merely that it throws them down more completely.

The alcoholic method of analysis may be applied to determine the amount of oxalates present in the urine. Thirty specimens of different urines (10 cc. to 15 cc. of each) gave an average of twelve oxalates of $\frac{1}{3000}$ in. in each field of view. All the oxalates were in about two to five drops at the bottom; there might therefore be from 20,000 to 100,000 of such crystals in 15 cc., or about 2,000,000 to 10,000,000 in 52 oz. of urine. The whole quantity probably does not nearly amount to 1 gr. per diem; but it must be confessed that the absolute measurements obtained by this method involve some data open to question, yet comparative results of great value may be obtained. Although, therefore, not able to give exactly the quantity of oxalates passed per diem, the following results give the comparative quantity at different periods. Ten specimens of "urina sanguinis" gave an average of 8½ oxalates of $\frac{1}{3000}$ in. in each field of view, whereas ten specimens of urine after breakfast on the same days gave an average of 22 similar crystals. They appear therefore to be increased by food, but in a very irregular manner, as the following table will show.

	Urina sanguinis.		Urina cibi (same day).
	17	... ...	5
	15	... ...	15
	6	... ...	13
	12	... ...	130
	5	... ...	2
	4	... ...	0
	2	... ...	26
	4	... ...	4
	18½	... ...	14½
	2¼	... ...	9
Average	8½		22

Here the variation of the oxalates in urina sanguinis is only from 2 to 18, whereas in urina cibi it is from 0 to 130. This is, no doubt, partly due to the more constant composition of the former, and its being more typical of the whole urine and less liable to sudden variations. But there can be no doubt that oxalates take some time for elimination: thus, the abnormally high specimen of urina sanguinis, marked 18½ in the above table, was from a case where some rhubarb had been taken on the previous day, about seven hours before bedtime. Possibly this is also expressed by 14½ for the urina cibi of the same day, and if so it will be difficult to judge of the influence of various articles of food on the production of oxalates, since the latter may be retained for some time within the system. From the same cause it is difficult to say what is the real source of the oxalates found in urine. Nearly all plants contain a certain amount of oxalic acid, though whether they manufacture this for themselves or obtain it ready formed from the soil, in many cases, does not appear; but whether this would account for all the oxalates of the urine is very doubtful, and the more so as there are many animal products from which oxalic acid can readily be obtained by decomposition. The chief of these is uric acid. There can be no doubt that uric acid is easily oxidised. The sum of its elementary constituents is 168; but in 20 experiments on its solution in soda it seldom gave more than 140 or 150 after ten minutes' boiling; and if this soda solution be acidified by acetic acid and filtered, so as to separate the remainder of the uric acid, a little oxalic acid can be found in the solution by $CaCl_2$, though almost none could be found in the original uric acid treated with soda in the cold. Though there can be little doubt, therefore, that a small quantity of oxalic acid is readily derived from uric acid, even by the simple oxidation of boiling, yet it does not appear that this process takes place at ordinary temperatures; at any rate, uric acid seems less readily decomposed than urea, for urate of ammonia is a common precipitate in ammoniacal urines, due to the $(NH_4)_2CO_3$ produced from the urea giving up its NH_3 to the precipitated and dissolved uric acid. Moreover, the experiments described at the beginning of this paper seem to show that this process does not take place as a fact at least within a reasonable time to account for deposited oxalates; but these experiments show nothing as to what may go on within the body itself, and it is therefore possible that uric acid oxidised within the body may give rise to oxaluria; but as there are so many other products from which it may be obtained a large number of facts will be required to prove this point. The most common form in which oxalates appear in the urine is the transparent flattened octahedron, where a line drawn between the two apices through the crystal is not more than half the length of one of the sides; they must therefore rest upon one of their faces, and thus by no possibility can the two apices be seen in the same straight line; they therefore appear envelope-shaped. But if the distance between the two apices is much greater, as it sometimes is, they can no longer rest on one of their faces, but lie upon one of their sides, and appear regular octahedrons. The greatest abnormalities of form are seen in the scum of urine, which often contains abundance of oxalates after the first few days. The majority of crystals deviate from the usual shape, some even appearing as dodecahedral; but they are usually smaller than at the bottom, and are deficient on one side or edge, doubtless from the crystallisation taking place at the surface, where it is exposed to disturbance from the air. It is not easy to explain why oxalates should appear at the surface of urine; but uric acid and triple phosphate do the same. It is probably, therefore, due to the capillary attraction of the innumerable vibrios which cover the surface, and which must cause some of the water evaporating from the surface to leave its salts behind entangled amongst them; but it must be confessed that the vibrios sometimes appear too few to support the weight of crystals superimposed.

College of Medicine, Newcastle-upon-Tyne.

The Board of Trade has again revised their scales of medicines and medical stores for emigrant ships. Two scales are now officially published, one to be used on North Atlantic steamships, when the voyage does not exceed thirty-seven days, and the second on all other passenger ships sailing under the Emigration Acts.

A SUCCESSFUL CASE OF OVARIOTOMY.*

By W. EASBY, M.D.,

SURGEON TO THE HOSPITAL FOR SICK CHILDREN, DARLINGTON.

Mrs. B——, a widow, aged fifty-six, first consulted me on Nov. 14th, 1873. She had enjoyed good health until two months previously, when she was seized with a pain in the right side. This lasted for two or three days, when it passed off. Since then she had not felt well. She complained of dyspnœa, and thought she was getting stouter. Appetite fair; bowels regular; urine scanty and full of lithates, did not contain albumen; pulse quick; second sound of heart rather prolonged. The skin was rather jaundiced. The abdomen was distended with fluid, and was dull upon percussion all over. The distension increased until January 4th, 1874, when I performed paracentesis abdominis, when eleven quarts of claret-coloured fluid were removed. After the abdomen was thoroughly emptied I could feel on the left side in the iliac fossa a tumour the size of an egg. It was freely movable, nodulated, and not tender on pressure. I was at once able to diagnose a multilocular ovarian tumour. During 1874 she was tapped twelve times. After each operation pressure was applied to the abdomen, and she took internally the muriated tincture of iron, and occasionally a few doses of Parrish's food. After each operation her recovery was rapid, and she never had any pain. Her general health kept fair, but not good enough, in my opinion, for operative interference. Towards the close of the year the cyst required emptying every fourteen days, and the fluid had changed from a claret colour to that of thin gruel. The largest quantity I removed was fourteen quarts. The solid part of the tumour had also increased in size.

As matters were getting almost daily worse and the only prospect for my patient was a miserable death in a short time, I proposed ovariotomy, to which she consented without any hesitation, and having secured the assistance of Drs. Fothergill and Middlemiss of this town, I operated on Jan. 31, 1875. Temperature of the room about 70°. Dr. Fothergill administered chloroform, which she did not take very well; two or three times her pulse got feeble and almost stopped, her jaw also dropped; when the flannel upon which the chloroform was administered was removed she rallied, but great care required to be exercised, and she was only kept very slightly under its influence. An incision four inches in length was made three inches below the umbilicus extending downwards to the pubes, and the sac carefully dissected down to. The adhesions were few, principally near the site of the tappings; these were easily broken down. One adhesion in the right iliac region was very firm, but after some trouble it gave way. The hæmorrhage from the separation of these adhesions was very trifling, no ligatures being required. Unfortunately, during the separation of some of them, the cyst was ruptured and the fluid escaped; very little of it, however, passed into the abdominal cavity. The pedicle was six inches in length, one and a half in breadth. It was secured by a double antiseptic catgut ligature passed through the centre and tied on each side; another similar ligature was firmly tied above the first, this was passed round twice and the two effectually prevented any hæmorrhage; the pedicle was then divided and dropped back into the abdomen. The tumour was multilocular and grew from the left ovary; emptied of fluid it weighed 2 lb. 9 oz.; the solid part of it was the size of a large kidney, and consisted of several large and small cysts varying from that of an egg to some very little larger than a pea. The edges of the wound were brought together by three deep sutures of thick silk; these were passed through the peritoneum. Between these were three superficial wire sutures. A large compress of marine lint was placed next the wound and over this a flannel bandage lightly pinned. A half-grain morphia suppository was pushed into the rectum and she was then removed to bed and covered with warm blankets; hot bottles were applied to the feet and sides of the chest.

---

* Read before the South Durham and Cleveland Medical Society.

She rallied well from the chloroform, which I may here say was given from a drop bottle, and the quantity used was seven drachms, the operation lasting about seventy minutes. During the remainder of the day she made no complaint, except of smarting pain in the abdomen. She never had any vomiting or retching, and when I left her at 9 P.M. she said she was quite comfortable. Pulse 110; temperature 101·2° F.; her temperature after the completion of the operation being normal.

Feb. 1st.—Has had about four hours' sleep during the night. Pulse 106; temperature 99·4°. Beef-tea enema. Catheter used; has no pain, no sickness; complains of a little soreness of the body. Enema repeated at bedtime.

2nd.—Had another good night. Wound dressed, which looks well; no pains or sickness; soreness of body much relieved. Pulse 100; temperature 98·4°. Had enema twice.

3rd.—Allowed her some milk by the mouth. Warm water enema was given to relieve the bowels. In the evening her temperature was 99·8°; pulse 116. Is taking beef-tea and milk freely. No sickness or pain.

4th.—Has had a fair night. Temperature 100·8°; pulse 120. Is suffering from vesical catarrh; urine full of mucus, and is passed with difficulty. Is taking beef-tea and milk freely. For the vesical catarrh I prescribed infusion of buchu, and hot fomentations were applied to the vulva and region of the bladder.

5th.—Slept well all night. Temperature 100°; pulse 128. Asked for fried sole to dinner. Removed sutures. Wound is healed, except about the eighth of an inch at the upper end.

6th.—Slept well all night. Is taking jelly, beef-tea, and milk, and a little champagne. Pulse 100; temperature 100 8°.

8th.—Still better; has no pains; can turn easily in bed.

12th.—Not so well; skin hot. Pulse 130; temperature 102°. Has no abdominal pain.

13th.—About the same; had a fair night; no pain.

14th.—About 5 o'clock A.M. the patient and nurse were alarmed by a gush of pus from the wound. There must have been about forty ounces; it was quite free from smell. In the evening her pulse was 106; temperature 98·4°.

15th.—Has passed a good night. Pulse 90; temperature 98·4°.

17th.—Got up for the first time, and was able to sit for an hour; wound is still discharging.

Since the last date she has made a good recovery, and is now able to follow her household duties; has improved very much in appearance, and had it not been for the cold weather would have been out of the house. The first two days after the operation all nourishment was given by the rectum, and the bladder relieved by the catheter. When all danger of vomiting had passed away I allowed her food by the mouth; this was the fourth day after the operation. No sponge was introduced into the abdominal cavity; a little fluid and blood were squeezed out by external pressure. We had no trouble with the intestines, only two inches of the small bowel being visible after the cyst was withdrawn. The cicatrix has now contracted to about three inches in length, and is barely visible. I ought to give my patient the credit of being one of the calmest women I ever met with, and her following out carefully my directions, with the excellent nursing of her daughters, have greatly contributed to her recovery, for which I need hardly say she is very thankful.

The Cholera in Syria.—The latest telegraphic advices which have reached the Sanitary Board in Constantinople indicate rather a diminution than otherwise, and especially in certain localities, of the cholera outbreak in Syria. At Damascus, from the 1st to the 8th ult., 51 new cases had occurred, and from amongst these and previous attacks, there had been 101 deaths. At Antioch, on the 1st and 2nd of August, there were 6 fresh cases and 4 deaths; no further attacks or deaths have taken place since the 2nd. At Aleppo, from the 2nd to the 7th ult., there were 152 cases and 104 deaths, and at Beyrout, within the same period, 69 cases and 45 deaths. At Lattakia, on the 5th ult., 3 attacks and 1 death occurred. Four cases of cholera are reported from Mount Lebanon, and Rustem Pasha, the governor of the mountain, has ordered all available sanitary measures to be resorted to.

GUY'S HOSPITAL.

CASES ILLUSTRATIVE OF SOME OF THE DISEASES OF THE RECTUM.

(Under the care of Mr. T. Bryant.)

We commence this week a series of cases illustrating some of the diseases of the rectum. The series will comprise cases of hæmorrhoids, prolapse, stricture, and cancer.

Case 1. *Internal hæmorrhoids; sloughing; cure.*—(The following notes were taken by Mr. T. F. Pedlay.) Joseph M——, a brewer's drayman, of good health, aged thirty, was admitted into Job ward on the 25th June, 1874, with a large portion of bowel protruding from his anus. It was very painful and bled a good deal when his bowels were opened, the motions being passed with great difficulty. He had had pain and slight bleeding on passing his motions for nine months. This increased, and, four months after, he became a patient in St. Thomas's Hospital, where he remained three weeks, going out much better; but the complaint returned, and he lost much blood every time he defecated. He seemed a strong, healthy man; was married, and had four children.

As he had been much confined in his bowels since admission and had great pain, he was ordered, on the 29th, confection of senna and also castor oil, after which the bowels were moved and the pain became less.

July 3rd.—The external folds disappeared quickly, and the man felt much better, the bowels being well opened.

6th.—The folds of mucous membrane had disappeared, having been healed by an entirely natural process, and he left the hospital cured.

Case 2. *Prolapsus of rectum; removal by galvanic cautery; improvement.*—(The following notes were taken by Mr. C. G. Lee.) Mary H——, a servant, single, aged thirty-eight, of good family history, was admitted into Lydia ward on the 5th July, 1873. Three years before admission she had a difficulty in passing her motions; they were in the form of hard lumps and caused her a great deal of pain, both in the act of passing and afterwards. She continued in that condition for six months; she was otherwise well. She was then taken ill, lost a great deal of blood from the bowel and was unable to pass anything; she had castor-oil enemata, but her bowels came down after every motion and she continued to lose a great deal of blood. She always was obliged to have injections to relieve her bowels. Her abdomen was very prominent.

July 14th.—The bowels were found on examination to be empty, although they had not been moved since her admission. She was ordered two ounces of the compound senna draught. The following morning they were slightly moved, but she passed blood after the motion. She seemed better.

16th.—She took one ounce of castor oil, and her bowels were moved without blood.

19th.—The patient looked better; her bowels were opened, but the motions were small and hard. She used an injection of soap and water and felt much relieved; her bowels were very sore, but she passed no blood.

22nd.—She was not so well; her bowels had not been opened after the injection as usual. She did not sleep well. Chloroform was administered; the extruding parts of the bowel were grasped with a clamp in two sections, right and left, which were cut off and the base well burnt with galvanic cautery.

23rd.—She looked very comfortable, but said the bowel felt very sore. She passed some small motions, with clots of blood, and did not sleep at all well. She said the bowel came down with the least movement; it was put up twice. Pulse 111; temperature 100·5°.

24th.—Patient woke up at 4 A.M. with cold sweatings and shivers. She felt very weak, and had hardly any appetite;

her bowels had not been opened, and came down but very little. Pulse 105; temperature 99·6°.

26th.—She had again cold, clammy sweats, followed by burning heat, and some pain over her stomach. Hot flannels were applied, and she passed a great deal of wind. She had not had her bowels opened since the 23rd, and complained of a lump in the right groin, which was very tender; it was about the size of a nut. No impulse could be felt when she coughed.

August 2nd.—She has remained in about the same state during the last few days. She felt great pain across the lower part of her abdomen, and had hot flannels applied. She complained also of sickness.

4th.—Her bowels had not been opened yet. She had a castor-oil injection, when four or five hard lumps came away. The pain had increased since her bowels were opened, and she was very sick. She had not much appetite, but her water passed easier.

5th.—She felt stronger, and her appetite had improved, but she could keep nothing down—it returned about an hour after her meals. She slept, however, without an opiate.

7th.—Sickness continued. She felt very weak, and complained of pain across the pit of her stomach. Her bowels were moved after an injection; the motions were very hard and lumpy, and slightly tinged with blood. The alternations of heat and cold returned, and she ate very little.

9th.—She was taking compound chinchona mixture, and felt a little better, but still very sick. Her bowels were well relieved after an injection, the motions being about the same, but without blood.

11th.—The patient was improving, and appeared more cheerful, but very sick. She sat up for the first time. No blood came away with the motion passed after injection.

12th.—She was better; the bowels had been again opened after injection; the motions were normal; had no pain, nor was any blood passed.

19th.—The patient was still improving, her bowels having been moved after injections, and without blood. Her appetite also was better, although she was sick in the night. She continued to do well, but the bowels were never opened without an injection. She seemed very comfortable, still the bowel came down a little.

26th.—She left the hospital.

CASE 3. *Very extensive prolapsus recti; application of galvanic cautery in stripes; cure.*—(The following notes were taken by Mr. Cusack.) Anna W——, a married woman, aged forty, of fair family history, was admitted into Lydia ward on Aug. 19th, 1874, with a large mass of bowel protruding from the anus, about the size of a cocoa-nut. She felt much pain, and seemed weak. She had suffered for fifteen years from the bowel coming down, but it had not given her so much pain; it bled very much at times, and she was also troubled with tapeworm and great relaxation of the bowels.

Aug. 25th.—By means of the electric cautery the surface of the protruding mass of bowel was cauterised in a linear direction, the stripes being made obliquely, and then returned, some small portions of mucous membrane above the sphincter being removed as the sphincters were found to be very feeble and relaxed. There was a little hæmorrhage the day after the operation, but it was stopped with ice. Temperature 99°.

Sept. 2nd.—The prolapsus had not come down again, but the bowels had not acted for some days. She took some castor oil, which relieved her, there being no blood with the motions. She complained of feeling weak, and also of pain when her bowels were opened. She had also a feeling of giddiness and lightness in her head. She was ordered on the 14th fifteen-drop doses of tincture of the perchloride of iron, and her pulse, which had been rather small (72), became much firmer (90).

Her bowels still being inactive, thirty grains of sulphate of magnesia was added to her medicine, when she became very relaxed, and she had no power at all to retain her motions. This difficulty remained some days. On the 22nd the prolapsus came down again about an inch, and continued to do so when her bowels were opened; but she has been able to go out in the air and gained strength, so that she left the hospital on Oct. 3rd.

Dec. 7th.—This patient came to Guy's to report progress. She said the bowel never came down now except when at stool, and then only when straining, and a very little. She never lost blood.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.

CASES OF GLAUCOMA.

(Under the care of Mr. POWER.)

THE following cases, for the notes of which we are indebted to Mr. G. Ernest Alford, are the commencement of the record of a series of cases of glaucoma that have recently been under treatment at the above-named hospital. Although the results may not appear brilliant, they were under the circumstances good, and their publication forcibly teaches us one lesson—namely, the imperative importance of operating as early as possible in such cases. But early operation implies early diagnosis, and on this point it must be confessed much ignorance still prevails—not, of course, on the part of ophthalmic surgeons; yet very little experience will suffice to show that few diseases are more readily recognisable than glaucoma.

CASE 1. *Acute glaucoma; attempted iridectomy; slight temporary relief.*—R. E——, aged fifty-six, a labourer, from Gravesend, was admitted on December 21st, 1874. He stated that his right eye had been getting dim for the last six weeks, and that he had had violent paroxysms of pain in it at intervals during that time. Both the dimness and the pain had much increased during the last week.

The iris was found to be widely dilated, so that it could scarcely be seen at all. Tension very high; globe of stony hardness, the pupil having the greenish opaque look very strongly marked. The man could not distinguish light from dark, much to his surprise, for he did not know that he was blind until told to cover the left eye. Fundus invisible, owing to the haziness of the vitreous. Left eye quite normal.

Having previously warned the patient that an operation would probably do little more than relieve the pain, which was very intense, Mr. Power endeavoured to perform an iridectomy on the right eye, under chloroform, but owing to the extremely dilated condition of the iris he was unable to seize it, and so was obliged to be content with lessening the tension by the escape of the aqueous through the incision. He was sent to bed, and both eyes covered for twenty-four hours. He had no more pain that evening, and slept well for the first time for many nights. On the second day he was allowed to get up for a short time, and one eye was uncovered. He had had no pain since the operation. The tension was decidedly less than formerly. He went out on the 24th of December quite free from pain, and just able to distinguish light from dark.

He again attended as an out-patient on January 18th, 1875. He could then just distinguish light from dark; the tension was slightly above that of the other eye; the pupil widely dilated as before, and he had had no more pain from it. The media were hazy, preventing a good examination of the fundus.

On Feb. 1st he was in the same condition.

When last seen, at the beginning of May, the tension was still greater than normal, and he was unable to see light. He said he occasionally had some pain in the eye, but very little.

CASE 2. *Simple glaucoma; iridectomy; partial recovery.*—Edward T——, aged fifty-six, a labourer from Westminster, was admitted on the 2nd of January, 1875. He complained of pain in his right eye and temple, and periodic mistiness of vision. He said the eye had been getting dim for two years, but that it had got rapidly worse during the last few weeks. The tension was slightly increased; no cupping was visible; his vision was $\frac{20}{70}$. An iridectomy had been performed on the left eye for glaucoma two years previously, and with it his vision was $\frac{20}{70}$. A solution of atropine (four grains to an ounce) was instilled daily, and he was ordered a mixture containing quinine, aconite, and colchicum. On January 11th he had so much improved that he was sent out for a week or two.

He again appeared on Feb. 13th, and was readmitted. He had had more pain in the eye. The fundus was just visible through a hazy vitreous, there was slight cupping of the optic disc, and the tension was a little above the normal. His vision was $\frac{20}{200}$ with the right eye and $\frac{20}{100}$ with the left. Unfortunately he came in too late for operation that day. He improved for a few days, and then had another relapse, so that Mr. Power did an iridectomy upwards, without chloroform, on Feb. 19th. Atropine was instilled, and a pad and bandage applied. It was dressed daily, and some atropine dropped in. He had no more pain, and on March 3rd his vision was $\frac{15}{70}$ with the right eye and $\frac{20}{50}$ with the left. The vitreous was clear, and there was no sign of cupping. On March 5th it was still improving: V = $\frac{20}{50}$ with a convex 36 glass, and $\frac{20}{70}$ without any glass, and he could read No. 4 Snellen with + 16. He has not been to the hospital since.

Case 3. *Simple glaucoma; iridectomy.*—Mary N——, aged sixty-five, married, with eight children, was admitted Jan. 15th, 1875. She stated that the sight of the left eye had been getting dim for nine months, occasional obscurations, lasting for a few minutes, coming on generally whilst at needlework. Her sight has been weak for the last twenty years, caused, she thinks, by suckling too long, and she has worn glasses during that time. Caught cold on Christmas day, and since then she had had severe pain in the eye and down the side of the face, accompanied by headache, and always worse at night, preventing her sleeping well. Very subject to rheumatic gout for years, all her fingers and toes being thickened and distorted at the joints. Her bowels have been very irregular for three years, generally constipated for days together.

On admission there was no perception of light in the left eye; slight sclerotic congestion; iris greenish, immovable; pupil dilated; tension much increased; T + 2; vitreous too hazy to allow of examination of fundus; pain in eye acute, constant, and lancinating.

Under chloroform Mr. Power performed an iridectomy upwards in the usual way. Atropine was instilled, and a pad and bandage applied. In the evening the pain was less than it had been for three weeks. Atropine was instilled daily, and she had no more pain. The tension was normal; the incision healed by cystoid cicatrix with considerable protrusion, which was somewhat lessened by a firm compress. She went out on Jan. 25th.

On Feb. 8th the eye was in the same condition, but more tense than when she went out. She had had no more pain. There was still no perception of light, and the humours were too hazy to enable one to see the fundus. It was in the same condition on March 5th.

LEICESTER INFIRMARY.

DISLOCATION OF THE SIXTH CERVICAL VERTEBRA FORWARDS, WITH FRACTURE OF RIGHT TRANSVERSE PROCESS AND TIP OF LEFT TRANSVERSE PROCESS; FRACTURE ALSO OF BOTH LAMINÆ; DEATH ON THE SEVENTH DAY.

(Under the care of Mr. Benfield.)

One of the chief features of interest in the following case was the great variation in temperature, the lowest degree observed being 94·2°, the highest 106·4°, giving a range of 12·2°.

David W——, aged forty-six, a carpenter, was admitted on May 29th (at noon), 1875. The patient, who was a heavy man about 5 ft. 10 in. high, fell from Blaby Bridge, a distance of 25 feet, while removing iron bolts from sidings. On admission there was impaired sensation and mobility in both arms, complete loss of sensation from lower end of sternum (extending upwards three inches behind) to inferior extremities. He could not move the legs in the slightest degree, and tickling the feet did not excite any reflex action. The breathing was chiefly abdominal. The skin felt cold to the touch, and the patient complained of cold. Well-marked priapism. At 2.15 P.M (two hours and a quarter after admission) the temperature was taken, and found to be 96·5°. At 7.15 it was still below normal, but at 9.15 (twelve hours after injury) it had reached 99·2°. The temperature during the day had been as follows:—At 2.15 P.M., 96·5°; at 3.15, 94·6°; at 4.15, 95·6°; at 5.15, 96·4°; at 6.15, 97·2°; at 7.15, 98°; at 9.15, 99·2°; at 10.15, 100·1°. At 10.40 P.M. the pulse was 68, full; respiration 20. Patient complained of the arms being very painful—pins and needles sensation. Right wrist was swollen from severe contusion. The catheter was passed; not more than four ounces of urine in bladder.

May 30th.—The temperature at 12.15 A.M. was 100·4°; at 2.15, 101·2°; at 4.15, 102·2°; at 8.15, 102·6; at 9.30, 103·2°. At 9.30 A.M. the pulse was 96, full; respiration 32. Face flushed and hot to feel; conjunctiva congested; skin of neck and ears also congested; carotids throbbing; tongue dry and fissured longitudinally. Patient was lying with arms semiflexed; if put straight, they soon assumed the flexed position. He could flex, but not extend, the forearm, but was not able to raise the arm from bed. No increased loss of sensation; had had no sleep during night.—10 A.M.: Mr. Benfield visited patient, and ordered one grain of calomel every four hours, with ice-bag to spine. The temperature now began to fall suddenly. Thus, at 10.50 A.M., it was 102·6°; at 1.15 P.M., 98·6°; at 3.15, 95·6°; at 4.15, 94·2°. The two armpits were now both taken, and with the following result: At 5.15 P.M.: right, 97·4°; left, 100·2°. At 6.30: right, 98·6°; left, 100°. At 7.30: right and left, 100°. At 8.30: right and left, 100°. At 9.30: right, 97·8°; left, 100·4°. At 10.30: right, 99·4°; left, 100°. At 11·30: right, 100·2°; left, 100·4°. At 4.15 P.M.: Pulse 54; respiration 20. Loss of sensation had increased, and extended from third costal interspace. At 8.45: Pulse 64; respiration 20. No extension of loss of sensation.

31st.—The temperature at the armpits was as follows:—At 12.30 A.M.: right and left, 100°. At 1.30: right, 100·6°; left, 101°. At 2.30: right, 100·2°; left, 101·4°. At 3.30: right and left, 101·4°. At 4.30: right, 100·8°; left, 101·2°. At 5.30: right and left, 100·8°. At 6.30: right and left, 100·2°. At 7.30: right and left, 100°. At 9: right and left, 100°. At 10.15: right, 100·4°; left, 99·8°. Pulse 68; respiration 20; skin warm and dry. The temperature fluctuated during the day between 100° and 101°; but at 9 P.M. it was in the right axilla 101·6°, in the left 105; at 10.30 it was in the right 101·2°, in the left 100°. Thirty ounces of urine drawn off.

On June 1st the temperature was 98·6°; pulse 64, rather full; respiration about 20, but the patient was troubled with such incessant cough that it was impossible to count them; the respiration, too, was almost entirely diaphragmatic. No increase of loss of sensation. At 3 P.M. the temperature was, right and left, 99·8°; at 9 P.M., right 99·6°, left 101·4°.

2nd.—Temperature 99·6°; pulse 80; respiration 24. No material change in symptoms. A large quantity of ammoniacal urine drawn off by catheter. Evening temperature: right, 98·4°; left, 97·2°.

3rd.—Has passed a restless and delirious night; not more than half-an-hour of sleep. Pulse 92, full; respiration 28; temperature 102°. Has had several slight convulsive twitchings of the arms and shoulders; complains much of pain in the shoulders and legs.—8.50 P.M.: Temperature of right armpit, 102·8°; left, 104°.

4th.—Slept about an hour last night after a morphia hypodermic, $\frac{1}{4}$ gr.; then was terribly restless and delirious.—9.30: Evidently sinking fast. Temperature 106·4°.—11 A.M.: Death, just six days and two hours after receipt of injury.

Autopsy.—Part of ligamentum nuchæ and interspinous ligament between sixth and seventh cervical vertebræ ruptured; transverse processes of sixth bared of ligament. On separating sixth from seventh, which was readily done, the ligamentum subflavum was found to be ruptured, and cord exposed for fully half an inch. The transverse process on the right side was completely fractured, as were also both laminæ. The tip of the transverse process on the left side was fractured. The cord was exceedingly soft and pulpy; unfortunately it was so destroyed in removing sixth vertebra that a satisfactory examination could not be made.

NEWCASTLE-ON-TYNE INFIRMARY.

(Cases under the care of Dr. Byrom Bramwell.)

Case 1. *Left Hemiplegia; Double Optic Neuritis and Syphilitic Choroiditis; motor power regained before sensibility; convulsion; death; syphilitic tumour springing from dura mater; extensive softening.*—R. S——, a man aged forty-one, was admitted on Nov. 12th, 1874, suffering from left hemiplegia. Patient had led a dissipated life for the past ten years; had been an opium-eater; had had syphilis. For the past year his sight had been failing. Three months ago he awoke one morning and found he had completely lost the use of his left arm and leg. Speech was slightly affected; the mouth was drawn to one side. Motor power slowly returned.

On admission, there was partial loss of motor power in the left arm, leg, and left side of the face. He could walk with a stick, and could raise the hand to his head. The tongue was protruded in the middle line. Tactile sensibility in the arm and leg was destroyed. He made no complaint when pricked with a needle. Mental condition was much impaired; memory seemed almost gone. His statements could not be relied on. He said he had no pain in the head, and had never had any. There was atrophy of both optic discs, and well-marked syphilitic choroiditis. Patient was stout and very jovial. His appetite was voracious. The heart, kidneys, and other organs were, so far as could be ascertained, natural. There was a well-marked node on the left tibia. He slept soundly, and passed his urine in bed during the night.

Under large doses of iodide of potassium he improved considerably; motor power was very greatly restored; sensibility partly returned; he could tell when the upper extremity was touched or pricked, but could not localise the impression.

Dec. 5th, 6th, and 7th.—Complained of severe pain in the head.

8th.—Had a severe convulsion at 10 A.M.; foamed at the mouth. The convulsion was followed by profound coma, which continued until he died, at 8 P.M.

At the autopsy, which was made eighteen hours after death, the dura mater was found to be firmly adherent along the vertex; it was much thickened, especially over the posterior part of the right hemisphere. A nodulated tumour, the size of a large walnut, was firmly attached to the dura mater at this point. The tumour pressed upon the right upper parietal convolution. The cerebral substance was softened, almost diffluent. The softening extended through the whole of the right upper and middle parietal convolutions, and invaded the upper occipital convolution. The membranes of the brain generally were thickened and opaque. There were a few cicatrices on the upper surface of the liver. The other organs were healthy. On microscopic examination the tumour was found to consist of small round cells and a few delicate fibres.

Remarks.—The chief point of interest in this case was the fact that motor power was regained before sensibility. This perhaps may be explained by the position of the tumour, for Ferrier has experimentally shown that the occipital lobes in the monkey and the middle of the superior external convolution in the rabbit are in all probability sensory, and not motor centres. It must also be remarked that in this case there was loss of memory and marked impairment of the mental powers. The absence of pain until a late period, and the absence of vomiting, are worthy of note. (The patient may have forgotten that he had pain in the early stages.)

Case 2. *Male Hysteria.*—R. W——, aged twenty-three, was admitted on 23rd October, 1874, saying that he was suffering from consumption. Had been for three years subject to fits; for three months had a cough. A few weeks ago he consulted a medical man, who told him he was labouring under consumption. He was a fish dealer by trade, and has been accustomed to carry heavy loads on his head.

On admission he was a tall, fair man; the hair of his head was very long, reaching almost to his shoulders. Had no hair on the face or chin. The state of general nutrition was good; the limbs were sound and well covered by fat, but not muscular. The genital organs were well developed. He spoke in a faint whisper. Was troubled with a frequent short dry "nervous" cough. The pupils were equal and widely dilated. No organic visceral disease could be detected. The bowels were costive. Pulse 72; temperature 98·5°.

Oct. 25th.—Had a severe fit at 6 P.M. last night; he threw himself about in the most violent manner and had to be held by five men. He foamed at the mouth when in the fit. The urine is copious and light-coloured. Ordered bromide of potassium and a purgative.

30th.—Complains of severe pain in the forehead, worse over the frontal sinuses than elsewhere; lies in a semi-stupid state; never speaks. Has had several severe fits; in some of the fits he rolls about the floor, but never hurts himself; never bites his tongue, but sometimes foams at the mouth. Pupils still widely dilated; radial pulse 100; temperature, axilla, 98·5°. Ordered galvanism to the larynx, valerianate of zinc, and a cold shower-bath daily.

Nov. 14th.—Very much better. Has not had a fit for several days. Says his voice is now natural; it is still very weak and woman-like.

18th.—Discharged well.

Remarks.—Dr. Bramwell had known this patient by sight for some years, and had frequently remarked his effeminate appearance. The case is a good example of hysteria in the male.

Reviews and Notices of Books.

On the Relation between Diabetes and Food, and its Application to the Treatment of the Disease. By Arthur Scott Donkin, M.D. London: Smith, Elder, and Co. 1875.

It is now some seven years since Dr. Donkin first drew attention in these columns to a new method of treatment in diabetes. It was a treatment which at the time excited some surprise and not a little scepticism, partly on account of its simplicity, and partly because of the novel theoretical basis upon which it was founded. In spite of this, however, it has been put to the test by many practitioners eager to adopt any remedial agent for a disease so intractable and so fatal. The result has not been wholly encouraging for the value of the skim-milk treatment, at least if we may judge from published cases. Some cases—like those recorded in this book—of success have been put upon record by other physicians; but, on the other hand, we hear of numerous failures, and some of our chief authorities have spoken in no measured terms against the method. We cannot, then, wonder that its promoter, with a zeal worthy of all praise, and confident in the truth of his researches and the value of his method, should again bring it under the notice of the profession; although he has but little to add to what is to be found in his first work, published in 1871.*

The present volume opens with an account of current opinions held concerning the pathology of diabetes mellitus, and, although differing from some of the conclusions enunciated by Bernard, he agrees in the main with the doctrine of glycogenesis, one of the crowning works of that illustrious physiologist. Dr. Donkin, however, is in error in stating that Bernard believes the destination of liver sugar to be in the lungs, for it is well known that he has abandoned this view which he first propounded, in favour of the more feasible one, that it is destined to be stored up as fat in the tissues, or expended in the production of muscular force. Dr. Donkin further shows that diabetes cannot be due to mere hyperglycogenesis (except when it occurs as transient glycosuria, which may well be termed "hepatic"), but to malassimilation of the glycogen-forming materials of food, by which sugar is at once substituted for glycogen—a view similar to that adopted by Dr. Dickinson in his recent work. But he is wholly at variance with Dr. Dickinson with regard to diabetes being a nervous disorder, and repeats in these pages his objections to the deductions drawn by that observer from the vascular changes he describes as occurring in the nervous centres of diabetics. We may remark, in passing, that these objections seem to be well founded, not only because the changes in question are equally well considered to be secondary to the disease, but because there is every probability that the traumatic disorder is not identical with the idiopathic; however great may be our desire to seek a structural change as at the root of what has hitherto been considered only a functional disorder. We must, however, dissent from Dr. Donkin in the statement that "the liver in diabetes is generally free from morbid changes"; we believe the converse to be true, and that, above all, it *does* show evidence of prolonged hyperæmia. Dr. Donkin then holds that there is a functional derangement of the liver, by which its cells secrete diabetic sugar directly, and he compares this sugar to a new formation or morbid growth, which, by reason of its crystalloidal nature, passes rapidly into the fluids of the body, and its being so carried far from its seat of formation renders it incapable of detection at this place.

---

* Skim-milk Treatment of Diabetes and Bright's Disease

The main object of this book is, however, not to deal with the pathogeny of diabetes so much as with its physiological phenomena; to show, in fact, that there is solid and good reason for the adoption of the skim-milk treatment. Abundant evidence is brought to show that this method, when properly carried out, is in a large proportion of cases capable of affording great relief to symptoms and often of effecting a cure. It has, however, been reasonably objected that skim-milk contains lactose, which, as a sugar, is contra-indicated, and is destitute of fat, which is generally held to be beneficial. This is, indeed, the main question at issue between the author of this book and those who differ from him, and he meets their assertions with a direct negative. What Bouchardat rejected as prejudicial—viz., milk,—on account of its containing sugar, Dr. Donkin accepts for the same reason; while he excludes cream, which was the constituent of milk included by Bouchardat in his dietary. With regard to the albuminous principle of milk, casein, this is of course retained by both parties; but Donkin declares that in the form of cheese it is prejudicial. Briefly he bases his reasons for this conclusion on one or two simple statements. The first is that lactose—an animal sugar—differs from the vegetable sugars and starches in not being assimilated as such, or metamorphosed into hepatic sugar, but as lactic acid. This being the case, it is curious that the lactic acid treatment introduced by Cantani has failed in good result, even in Dr. Donkin's hands. The reasons he gives for the exclusion of cream—hitherto included in all diabetic dietaries—apply to all fats of whatever description. They are based on the researches of Van Deen, Poggiale, and Salomon, which point to the fact that glycogenesis occurs even on pure fatty diet. But the author appears to be unmindful of the previously opposite results obtained by Pavy, McDonnell, and others, which have gone to confirm the prevalent idea that fats can be given to diabetics with impunity, and even with benefit.

The various chapters of the work are occupied with the demonstration of these views. In the first place it is shown how diabetes results from the malassimilation of vegetable and starchy foods, next of oleaginous, and, lastly, of albuminous foods. The last chapter is devoted to an exposition of the treatment. The author rightly insists upon its being carried out strictly, as, indeed, merely as a therapeutical experiment, it should always be; but we cannot follow him in his insinuation that its failure in most cases has been due to negligence or want of strict supervision of the patient. The quantity of skim-milk to be administered must not exceed twelve pints (less to commence with), and must be regulated by the age, sex, size, and state of the patient. If more casein is required, this may be supplied in the form of curds, and he combats the taunt that it is a "starvation method" by showing that the quantity of albumen thus administered is really all-sufficient (i.e., if it be all assimilated), and that patients gain in weight under its administration. As a general rule, he has found the sugar to disappear from the urine within five or six weeks (a fortnight is the usual time he states). If the disease be too advanced the treatment will not effect a cure, but will relieve the patient's condition to a vast extent. In such cases, and in cases where the skim-milk has been attended with success, he resorts to restricted diet, based much on the long recognised principles. A few illustrative cases are given, which have been recently recorded by other physicians, as instances of the value of the treatment; and we can only say that if they be not cases of hepatic glycosuria (to the existence of which Dr. Donkin is fully alive, as is shown in the opening sentences of the book), and to be considered as genuine examples of diabetes mellitus, they are valuable evidence in support of his theory.

We do not pretend to decide upon the efficacy of the skim-milk treatment. Certainly there is plenty of evidence adduced in its favour in this little volume, which renders it incumbent upon those who have not tried the remedy to apply it as the writer directs. But, at the same time, we must warn them not to carry the treatment too far, for even the author confesses that it is not a panacea for all forms of the disease, and the result may be disastrous both to physician and patient. Nor must we forget that cases of diabetes have been cured before now on restricted diet. The author seems to us to be under the impression that the treatment he advocates has not had a fair trial, but we think he is hardly just in his criticism of those who prefer the older methods; while with Dr. Dickinson, who dismissed the subject in a few curt sentences, he is especially angry, and administers a rebuke to that physician in the form of a solemn protest against "irrational investigators."

In fine, we commend this book to all who are interested in the subject; they will find it readable, and they may be convinced, for the author writes with the earnestness of conviction himself.

A Dictionary of Chemistry and the allied Branches of other Sciences. By Henry Watts, B.A., F.R.S., F.C.S. Assisted by eminent Contributors. Second Supplement. London: Longmans. 1875.

Although there is a gap of nearly thirty years in the pedigree, Watts's Dictionary of Chemistry is a lineal descendant of Ure's Dictionary, which for so many years was one of the most highly esteemed of English scientific handbooks. The vast increase in size which it has sustained, and the disappearance of all but a few paragraphs of the original text, mark the enormous development of chemistry during the interval. In its new form the work was completed in 1868, after nine years of careful work. The five large volumes were followed in 1872 by a supplement of over 1000 pages, in which the corrections which time had rendered necessary were supplied, and the record of chemical discovery carried down to the end of the year 1869. Three years have passed, and now a second supplement, even larger than the first, appears, and continues the great chemical history to the end of 1872. It would at first appear that at this rate another supplement must already be wanted, and there would seem to be no prospect of end to the growth of the book. Further increase, however, is in reality unnecessary, for since the year 1871 the Chemical Society of London has published in its monthly journal a series of abstracts of all important papers on chemistry and its allied sciences, both English and foreign; and this journal is so well arranged and edited that the yearly volumes, with their copious indices, will supply the place of future supplements to Watts's Dictionary. When a new edition of the work is required we trust it will be found possible to abandon the system of publication in parts, and issue it at once in a complete form. Much inconvenience would in this way be avoided.

The period of time covered by the new supplement, though fertile in chemical research, did not witness the birth of many really great discoveries. Hundreds of new compounds were of course obtained, particularly in organic chemistry; old laws were revised and some new ones brought to light; but nothing transpired that seems likely to effect any radical change in chemical thought. One great tide of discovery sets towards the physical side of chemical phenomena. Possibly the greatest secrets lie in this direction, and the results gained by Quincke, Valson, and others in regard to capillarity, by Berthelot (whose name must ever be mentioned with the highest honour) and Thomsen on heat of combination, and by Mills, Berthelot, Favre, and Deville on the conditions of chemical action, are examples of the material which is collecting for future use. Another great labour of the time is the determination of the constitution of organic compounds. The theoretical conceptions which first gave an intelligible explanation to the facts of isomerism are gradually throwing light on the most complex compounds, and have hitherto proved of the utmost value in suggesting methods of research and indicating probable means for new synthesis. Terrible names continue of course to abound. We are introduced to *orthochloroparachlororthamidophenol*, to *diacetylphenanthrenehydroquinone*, and the like, but we all know that they are necessary and really simpler than any empirical terms would be.

Physiological chemistry is well represented in the volume. Some of the articles are by Dr. Newell Martin, of Christ's College, Cambridge; but the editor contributes many, and all good. Thus we find, under "Blood," an account of Schützenberger's method of determining oxygen; and, under "Milk," an epitome of the most recent methods of milk analysis. Mr. Warrington's articles on agricultural chemistry are also excellent; and the same may be said of nearly every article we have inspected.

Altogether, it will be seen that the volume is a most valuable contribution to scientific literature; and, taking the work as a whole, we can but congratulate editor and publishers alike on their noble and colossal achievement.

The Commercial Handbook of Chemical Analysis. By A. Normandy. New Edition, enlarged and to a great extent rewritten by Henry M. Noad, Ph.D., F.R.S., Lecturer on Chemistry at St. George's Hospital. London: Lockwood and Co. 1875.

Dr. Noad has greatly improved this well-known handbook, and has done his best to bring it down to the present state of chemical knowledge. The alphabetical arrangement is wisely retained, and the analytical methods described for the most part well chosen and clearly described. Some important omissions occur, among which we may mention at random, paraffin and petroleum oils, benzene, turpentine, mustard, tobacco (often adulterated with liquorice), oil-cake, coal, and the use of the polariscope in the analysis of sugar. On the other hand, the editor has, we think, erred in including such methods as those for the complete quantitative analysis of the ores of cobalt, platinum, iron, and copper, and the assay of silver and gold. Methods like these are described in all manuals of analysis. No one but an experienced chemist would be likely to undertake them, and he would be sure to have larger manuals at his command. The space so saved might have been devoted to subjects proper to the scope of the work, and its utility thereby increased. In spite, however, of these blemishes, the book is a good one, and will be useful, not only to the manufacturer, but also to the professional chemist. Dr. Noad has greatly extended the glossary, which now contains many valuable hints on manipulation, and clear descriptions of the more ordinary forms of apparatus. That great essential, the balance, is, however, somewhat unaccountably omitted.

Vaccination Grants.—Mr. T. Taylor, of Bocking, has received the "extra vaccination gratuity," amounting to £15 17*s.* Mr. J. C. Leach, Sturminster Newton, has received a grant of £8 16*s.* for efficient vaccination (second time).

CHLOROFORM OR ETHER.

To the Editor of The Lancet.

Sir,—As the comparative merits of ether and chloroform are now under discussion, and the subject is one, moreover, of paramount interest and importance, the following case may not prove uninteresting, illustrating as it does two very prominent features in ether inhalation.

Two years ago I had occasion to operate on a woman into whose larynx I had one year previously introduced an ordinary tracheotomy tube for organic stricture. As she was reduced to the last verge of weakness it was decided to administer ether. This was given through the tracheal tube, by means of a cone of stiff paper and a sponge. It acted beautifully, sleep—calm, peaceful sleep—being at once induced. The pulse, from being quick, small, weak, and rather irregular, became slow, full, and vigorous—just such a pulse, in fact, that gives to the country surgeon perfect comfort and confidence. In this case the vapour must, of course, have entered the larynx directly, yet it did not seem to cause the slightest irritation, as there was neither gasping, coughing, nor other symptom of laryngeal disturbance. As the tracheotomy tube had been in one year, it is just possible the mucous membrane of the air-passages had become less sensitive. Be this as it may, the fact stands prominently forward that the ether vapour did its work efficiently, safely, and with apparently less discomfort to the patient than if it had been given by the mouth.

I hope I may not be considered presumptuous in coming to the front when so many experts are already in the field of discussion, but in a question of such vital importance one well-attested fact is always valuable; and from some of the letters which have already appeared on the subject, I consider this case not devoid of value, inasmuch as it shows that ether may be inhaled *directly* into the larynx without causing bronchial or laryngeal disturbance.

I am, Sir, yours truly,
James More, M.D.

Rothwell, Northamptonshire, August 29th, 1875.

THE LATE DR. MAUNSELL.

To the Editor of The Lancet.

Sir,—The announcement, in your last week's issue, of the premature death of Dr. Maunsell, of Dublin, is the heaviest blow and greatest discouragement which the cause of Poor-law medical reform has sustained since the day when poor Richard Griffin broke down. To me Dr. Maunsell's death is especially unfortunate, for he constantly afforded me most valuable aid in procuring statistics, notably as regards the administration of dispensary medical relief. On my first visit to Ireland six years since, undertaken for the purpose of studying the working of the system followed in that country, Dr. Maunsell was my companion and guide; indeed, without his assistance it would have been wellnigh impossible for me to have succeeded in obtaining any information. He was the originator of the Irish Poor-law Medical Officers' Association, and in his capacity of honorary secretary devoted himself with untiring energy to the realisation of its objects—viz., the improvement of the status and emoluments of his colleagues, and their superannuation. I doubt not that some effort will be made in the "sister isle" to show how much his great services have been appreciated, but in this country I feel we owe him something also. There can be no doubt that to his writings much of the success which has attended the efforts made to ameliorate the position of the Poor-law medical service is justly due,—notably as regards superannuation allowance.

That he has left his wife and young family in very indifferent circumstances there can be no doubt, and I therefore do hope that members of the profession in the United Kingdom will evince their sense of his public work *in their behalf* by contributing to a fund for their benefit.

For this purpose I shall be most pleased to receive any amount which may be forwarded to me.

I am, Sir, yours obediently,
Dean-street, Soho, August 30th, 1875. Joseph Rogers.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 4, 1875.

THE meeting of the British Association at Bristol presents, perhaps, fewer topics of interest to members of our profession than has often been the case at previous gatherings. The tone of the meeting is sensibly influenced by the presidential address, which this time was devoted to a review of the salient points in the history of a mechanical, although perhaps the grandest mechanical profession. In some points, indeed, the sciences of civil engineering and of medicine have an analogy; both have to deal with forces very much beyond immediate control—to guide where they cannot thwart, to divert where they cannot arrest, and often to meet with unforeseen and impassable obstacles. A retrospect of medicine will indeed compare in some respects favourably with the retrospect of engineering. If our forward steps are halting and slow, we have, at any rate, the consciousness that we have reached the highest point of knowledge and of power the history of our art presents, and have to look back on no monuments of an ability we cannot rival and a greatness we cannot achieve.

The subject of the very able address of BALFOUR STEWART, in the section of Mathematical and Physical Science—the physics of the sun,—is one which has no very distinct connexion with the treatment of disease. But there are not wanting indications that the indirect influence of the sun on the occurrence of disease may be found some day to be much more extensive and important than is at present suspected. In illustration of this we may refer particularly to the paper by Professor STANLEY JEVONS, read before the Economic Science Section, on the Influence of the Sun-spot Period on the Price of Corn. The distinct periodicity so often observed in commercial matters, prices of produce, monetary panics, and the like, suggested to him a further and more detailed comparison, which shows that, while the period of variation in the sun-spots is 11·11 years, the interval between the principal panics is 10·8 years, and the periodicity in high price of provisions was formerly the same. The intimate connexion of the meteorology of the sun and the earth was also ably discussed by BALFOUR STEWART. He traces, besides the ordinary light and heat effect, a peculiar magnetic and meteorological influence depending somehow upon the rotation of the sun, and also a cyclonic effect depending on the disturbed state of the solar surface. All three of these conditions, with the exception perhaps of the magnetic influence, are, as is well known, important agencies influencing the occurrence of disease. It seems as if the supposed influence of the moon on the terrestrial meteorology were about to be transferred to the sun. It may possibly be found that a similar transfer may have to be made of the imagined connexion between lunar influences and some phases of periodic maladies.

Of Professor ROLLESTON's admirable and eloquent address in the department of Anthropology we cannot now speak. In part more strictly scientific, it was also an able vindication, founded on scientific method, of the doctrine of human progress. A comparison of averages leaves the improvement in mind and morals quite unquestionable. The development of organic beings has, according to Professor CLELAND's address in the departments of Anatomy and Physiology, reached its highest point in man. "Animal life has attained its preordained climax in humanity." His remarks upon the confused system of nomenclature in comparative osteology, which he lamented as so puzzling and repelling to the student, will probably be thought in a few weeks' time, by not a few students, to be equally applicable to human anatomy. He concluded with a vindication of the scientific position of anatomy, and an earnest appeal for its instalment in its due position as an important element in a scientific education, expressing his somewhat enthusiastic opinion that it is even yet destined to take the highest place among the sciences as a guide to philosophy! In this department an interesting paper was read by Dr. HALLETT, of Bristol, on the Bearings of the "Conservation of Forces" upon Life. With great ability and subtle thought, he opposed the inclusion among the correlation of forces of those of vital action, urging that the logical outcome of that doctrine was the prospect of the ultimate destruction of the universe by the conversion of all forces to one dead level.

Of more direct interest to us is the report of the committee appointed to investigate the conditions which influence the intestinal secretion, which was presented by Drs. BRUNTON and PYE-SMITH. The results obtained by the experiments tend to show that neither the splanchnic nerve, the pneumogastric, the sympathetic above the diaphragm, nor the spinal cord, has any influence on the intestinal secretion. They render probable the influence upon it of the solar plexus, including, but not confined to, the semilunar ganglia. The absence of relation between the hæmorrhage and the secretion when paralysis of the nerves has been produced seems to point to a separate influence on the blood-vessels and on the secreting structures of the intestines. A paper on the Effects of Drinking-waters upon Animals, by Mr. W. J. COOPER, contained little of new or special interest beyond some experiments on the effect upon rats and other animals of certain artificial drinking-waters.

Among papers in the Economic Sciences Section we must notice that read by Dr. F. J. MOUAT on the Value of European Life in India. Within the present century the annual loss of life has gradually and steadily decreased from about 60 per thousand to an average of 15 or 16, and the decrease is still in progress. Among officers, from 1861 to 1870 the death-rate from all causes was not quite 17 per thousand; and among European railway *employés* the mortality was only about 10 per thousand. The improvement in the death-rate is due to causes which will probably be permanent, and may be in large measure ascribed to the influence and advice of the medical staff, wiser modes of living, improved sanitary arrangements, and more careful invaliding when early symptoms of disordered health appear. We should, however, like an explanation of the better health of the railway officials compared with that of the military officers. Each is a carefully selected body; each has a large amount of exposure to unhealthy influences, solar and terrestrial; and it is difficult to believe that any difference in habit of the two classes can account for the different mortality. Such was, however, the explanation offered by some subsequent speakers, who epitomised the worst antagonistic influences to European health in India as "brandy and soda." The excessive mortality among women and children adds, of course, very largely to the average, and seems to be, in the case of children at any rate, almost irremediable.

The statistics of Mr. Vivian on the Influence on Life of Total Abstinence, as evidenced by the tables of an insurance office in which the records of total abstainers and those of other cases were kept separately, are considerably in favour of the former. According to him, the deaths in nine years in the temperance section were about eight-elevenths of the expected deaths, while in the general section the deaths were only about one-seventieth below the calculated number. He did not, however, give the respective numbers of each class, on which all the value of the figures depends. Nothing is more fallacious than the publication of an average from a small number. The general impression in life offices is that total abstainers are bad lives, because they are so often reformed drunkards. Those who have been abstainers from youth are probably, other things being equal, better lives than those who are not, for they are withdrawn from one great cause of mortality which creeps insidiously among the best-selected lives. It is probable that to an office which is ostensibly in part a temperance one a larger proportion of life-long abstainers are attracted than to the ordinary offices.

It is satisfactory to learn that private munificence is to supply the absent funds for a continuation of the chemical analyses connected with sewage experiments. According to Mr. J. C. Melliss, the sewage problem, so perplexing to many towns at the present moment, has been solved at Coventry in a very satisfactory manner. The purification of the sewage and manufacturing refuse is effected at a cost for chemicals of £2 12*s.* 10*d.* per million gallons, and a manure is obtained worth 35*s.* per ton. The total cost is 5*d.* or 6*d.* per head of the population. The removal of noxious materials is at present most effective; the effluent water is described as clear and bright, of a high standard of purity, without perceptible smell, and almost free from colour. We are not surprised to hear that all parties concerned are well satisfied at such a result.

Auscultation of the heart, without doubt, forms one of the most interesting studies for the clinical observer, and the precise significance to be attached to the various murmurs heard in valvular disease of that organ has afforded matter of debate since the time of Laennec and Corvisart. Nor is it to be wondered at that such debate should still be going on with regard to these abnormal sounds, seeing that even yet physiologists by no means agree as to the causation and time of occurrence of the normal sounds, as to how far they are of direct valvular origin, or how far the muscular walls or the fluid contents of the heart itself participate in their production. The murmur which, above all others, has the most given rise to discussion is that styled "presystolic," which, when fully developed, is at once most characteristic and significant of the lesion underlying it—viz., obstruction to the flow of blood through the mitral orifice. Our own columns have frequently been the arena of discussion upon the nature of this murmur, and but recently we have had the question revived in a somewhat novel and singular manner. We do not intend to stop to examine critically the views propounded (to our thinking, somewhat too lightly for scientific debate) by Dr. A. Harvey in his recent contribution (The Lancet, vol. i. 1875, pp. 819 and 852); for, as Dr. Gairdner (vol. ii., p. 48) pointed out, all Dr. Harvey's arguments are based upon what is to him a mere assumption and not existent in fact. For confessing that to him the presystolic murmur has no existence, he forthwith proceeds to argue *ex hypothesi*, and to demonstrate on theoretical grounds that it could not have the physical cause assigned to it. The paper in question, however, did good in producing the clear exposition by Dr. A. Carter (p. 203) of the clinical facts; and, although we doubt whether there is one physician out of a hundred who is of Dr. Harvey's opinion, we are grateful for the results of his contribution.

The chief ground for debate, however, is that raised in our columns three years ago by Dr. Barclay, as to whether the murmur in question be not really due to the flow of blood backwards from the ventricle—in fact, that it be of regurgitant and not of obstructive nature, and therefore produced by no contraction of the auricle, or even passive venous flow from the auricle to the ventricle. In his closely reasoned argument, Dr. Barclay endeavoured to show that the auricular contraction passes continuously onward into the ventricular, and that preceding the forcible systole of the ventricle there is a period of tension of its walls, during which, in cases of thickened and contracted mitral orifice, the blood is poured back into the auricle, thus delaying the first sound of the heart, which is coincident with the systole, and which terminates the murmur abruptly. He further argued that the hypertrophy of the auricle so frequently attendant on mitral stenosis is not due to the increased work it would have to perform in forcing the blood through a narrowed orifice, but that it is rather due to the increased amount of blood delivered into the chamber; since, he said, if it contracted at all, it would empty itself in the direction of least resistance—viz., into the pulmonary circulation, in consequence of the pulmonary veins being unguarded by valves. Doubtless this always occurs to a slight extent; but it is equally true, as was pointed out by Dr. Balfour at the time, that, the pulmonary circuit being closed, there is a considerable amount of tension on this side, sufficient—in all, perhaps, but the most extreme cases of stenosis (and in these the characteristic murmur is frequently absent)—to neutralise the resistance afforded by the narrowed outlet.

We wish, however, to call attention to the most recent work on this subject by Dr. Galabin in his paper "On the Interpretation of Cardiographic Tracings," in the last volume of Guy's Hospital Reports. We have here the presystolic murmur put to the test of the cardiograph, the result being a strong confirmation of the view taken by Dr. W. T. Gairdner, and held by the large majority of clinicians,—that the murmur is "auricular-systolic" in nature. The paper is illustrated by a large number of tracings, and all of them clearly show that in cases where there was clinical evidence of mitral stenosis the contraction of the auricle occurred earlier, was more pronounced, and lasted longer than in health; besides confirming the view of MAREY (in opposition to that of FICK), that the auricular systole is concluded before that of the ventricle begins. Criticising the view of Dr. BARCLAY in the light afforded by this research, Dr. GALABIN points out that if the murmur in question be indeed due to regurgitation, and therefore occurring with the first act of contraction in the ventricle, then in such cases the carotid pulse ought to precede the first sound of the heart, and the action of the ventricle must be prolonged in such cases, both of which effects it is known do not occur. Dr. GALABIN does good service in pointing out that the term "presystolic" is open to question, that Dr. GAIRDNER'S term of "auricular-systolic" is preferable, and that, strictly speaking, it is diastolic with regard to the state of the ventricle; and he shows—what we have indeed observed at the bedside, but have never had an opportunity of verifying in the dead-house—that in some cases there may be a pure diastolic murmur—i.e., a murmur occurring after the second sound, but terminating before the first sound, heard only at the apex of the heart, and unaccompanied by any of the signs of aortic regurgitation. Such a murmur is presumptive of mitral contraction, but yet it does not conform to the presystolic type. That it is due to mitral contraction is borne out by the cardiographic tracing afforded in such a case, and its occurrence is explained by Dr. GALABIN on the hypothesis that the passive venous flow from the auricle, due to the high state of tension in the pulmonary veins, may give rise to a murmur as the current passes through the narrowed orifice; a murmur which disappears when the pressure in the ventricle equalises, or nearly so, that in the auricle. This, we think, is a most important fact, and one to which we direct Dr. BARCLAY'S attention; but at the same time we must admit that such murmurs are conspicuous by their rarity, and that the commonest of all the abnormal sounds indicating mitral contraction is that which begins before the first sound of the heart, and, increasing in intensity, terminates abruptly in that sound, and that this *is* due to auricular contraction we think no doubt can remain in the mind of him who studies Dr. GALABIN'S essay. There remain doubtless, further refinements in cardiac auscultation to be one day elucidated—e.g., such modifications of the sounds as may be produced by the minuter changes in valves &c.; but surely the day is passed when we can no longer diagnose manifest obstruction at any of the orifices of the heart.

◆

ACTS OF PARLIAMENT are not usually light or pleasant reading, particularly in the dog-days; but as so many of our readers, as well as the public generally, are interested in the buying and selling of food and drugs, the submission of a summary of the Sale of Food and Drugs Act, which will come into operation on the 1st of October next, cannot be deemed by any a work of supererogation.

There are thirty-six sections in this Act, all former enactments relating to the subject being henceforth repealed. The authorities appointed to carry out its provisions are the Commissioners of Sewers for the City, the District Boards for the rest of the metropolis, the Court of Quarter Sessions of every county, and the Town Council of every borough having a separate quarter sessions or a separate police establishment. In Scotland, the authorities are the Commissioners of Supply for counties, the Commissioners or Boards of Police, and the Town Councils for boroughs; and in Ireland the authorities are the grand juries of counties and towns and the Town Councils of every borough. Each and all of these authorities may or, when required to do so by the Local Government Board, shall appoint an analyst, who, on receipt of a sum not exceeding half a guinea, shall analyse any article of food or drug, the purchaser notifying to the seller his intention respecting it, and dividing the article into three portions, there and then to be sealed and marked, and held respectively by the vendor, the purchaser, and the analyst. All medical officers of health, inspectors of nuisances, weights and measures, and markets, or any police constable, may direct an analysis at the cost of the local authority; and a penalty is attached to the refusal to sell for the purposes of analysis any article exposed for sale. The analyst is required to report quarterly to the authority appointing him the number of articles analysed and the results, copies of which are to be transmitted to the Local Government Board. The offences under the Act include mixing, colouring, staining, or powdering any article so as to render it injurious to health, performing the same operations so as to affect injuriously the "quality or potency" of any drug, or selling any articles that have been so treated, exemption being allowed if ignorance of the fact be proved. Also no article is to be sold that is not "of the nature, substance, and quality demanded by the purchaser"—harmless ingredients required for "the production or preparation of any article," "proprietary" medicines, and food or drugs unavoidably mixed with "some extraneous matter in process of collection or preparation," being excepted. Also no person must, without notice, abstract any part of an article of food so as to affect its quality injuriously; exemption being, however, allowed, if the label indicates any change in bulk or quality. Proceedings against offenders may be taken by the person who has caused the analysis to be made, the certificate of the analyst being *primâ facie* evidence for the prosecution, but the analyst to give evidence if required. The justices may reduce or mitigate any penalty imposed, and may also at the request of either party cause the article to be examined by the analysts of the Inland Revenue Department at Somerset House. A further appeal is also allowed to the general or quarter sessions. Provisions are made against forging or misapplying a certificate or warranty, and for giving false labels. There are two special sections relating to tea, which recite, in effect, that on and after the 1st of January next all tea imported as merchandise into Great Britain and Ireland shall be subject to examination by officers of the Customs; and if such tea is found unfit for human food, it is to be condemned and destroyed, or otherwise disposed of as the Commissioner of Customs shall direct. "Exhausted" tea is defined to mean "any tea which has been deprived of its proper quality, strength, or virtue by steeping, infusion, decoction, or other means."

The weak points of the Act are not far to seek. The exemptions are so many and various that the chances of the escape of the defendant are by no means few. Indeed, as it appears to us, the 5th and 6th sections are specially framed to enable the vendor to wriggle out of a conviction. Section 22 will practically make the Laboratory Department of the Inland Revenue a court of arbitration in all cases of dispute, which will be numerous, so that the officers will doubtless have plenty of work to do. We again take leave to record that (and particularly as regards the provisions of this Act) the duties of medical officer of health and of analyst are incompatible, and cannot be properly or successfully performed by one and the same person. We trust that in a short space of time these dual appointments will have ceased to exist.

◆

THE ostrich buries his head in the sand in the presence of danger no doubt because that is the readiest mode of shutting his eyes to a difficulty he has neither the courage to face nor the wit to avoid. Our own policy in many grave emergencies is substantially the same. If a few sheep or oxen imported for food exhibit symptoms of a malady which must render their flesh not only unwholesome but perilous to consume, we kill off the entire herd or flock and sell the carcasses as quickly as possible, lest they, too, should turn out to be infected and therefore unsaleable. It is no concern of ours that probably — if there were any real grounds for apprehension as to the health of the herd—the animals slaughtered are, in point of fact, poisoned and incubating the disease, and that it is infected meat we allow to be sold to the public. At the moment the animals are killed we presume them to be technically healthy, although it is the misgiving that they may be infected which prompts their immediate sacrifice. In like manner, if a servant resident in a family is supposed to be sickening for some infectious disease, she is hurried away lest the supposition should be realised, and, the nature of the malady being actually known, it may be impossible to get rid of her. In all these cases refuge from the difficulty is sought in blindness to consequences. We fear the evil, and intentionally shut our eyes to the danger it threatens. The device is not without plausible excuse, and it enjoys a measure of success or it would scarcely be tolerated. No case of blood-poisoning from eating meat hurried to market to avoid the discovery that it was unfit for food has been recorded; and instances in which a neighbourhood is poisoned with disease blindly sent into it are not, as a rule, obtruded on public notice or allowed to scandalise the sense of decency. Exceptions do, however, occasionally occur, and one of them has found its way into *The Times*, to be followed most likely by others equally or even more sensational. The case, reported by a clergyman, possesses no special feature. A servant suffering from malignant fever, as the event proved, was sent home to her friends in the country—no doubt with benevolent intentions. She carried the disease into her family, and her own life and two other lives were sacrificed. Eleven cases in all formed the group of which this one, quietly put away out of sight by the persons who first *suspected* its real nature, was the seed and centre. We have no thought of moralising on the "indiscretion" or pouring out vain lamentations about the "untoward accident." If there had not been some fear that the girl was affected with an infectious disease she would not have been sent away. The circumstance that the fear entertained was well grounded is creditable to the forethought of those who rid themselves of the danger. It may not reflect the same credit on their humanity as on their sagacity; though even in this regard much may be said for those who keenly remember that charity to the human family begins at home, but forget that it does not end there. We do not think anything is to be gained by lecturing the public. Self will always be first, and it is generally all, with the best of us. The more practical consideration is, whether it would not be well if, attached to each hospital, or located in suitable districts in blocks by themselves, there were wards, appropriately furnished, where persons suffering from anomalous attacks, not sufficiently advanced to admit of diagnosis, might be instantly received, on small payment, without obtaining an "order" or any other troublesome preliminary, and where they might remain under proper expectant treatment until such time as the attack terminated or developed itself. A convenience of this nature would be greatly appreciated by the public; it would also prove singularly useful to the family practitioner, who is now often sorely pressed to advise his client as to the instant removal of a case occurring among the domestics, concerning the precise nature of which he is at the moment doubtful, but which he has no wish to send into a hospital or to remove from his own supervision before its character becomes apparent. It is of the essence of our suggestion that the wards should simply provide shelter and suitable appliances of nursing, and that the cases sent in should remain, if desired, under the medical care of the practitioner by whom they were introduced. We throw out the hint as a possible solution of a grave and pressing difficulty.

Annotations.

"Ne quid nimis."

THE ARMY MEDICAL SERVICE.

MR. GATHORNE HARDY, like the rest of the world, is probably at this time enjoying a *dolce far niente* life after his official labours, although it has been rumoured that the War Office was to be employed during the recess in evolving some new scheme of military organisation or in modifying and perfecting that left by their predecessors. It is to be hoped that one of the first announcements on the meeting of Parliament will be that Mr. Hardy has made up his mind what he intends doing for the Army Medical Service. The War Minister must have given the subject his full consideration, for, according to his own showing, he has taken his time about it; but we have not been able to gather anything from his statements, so far, beyond the fact that he seems very indisposed to introduce a system of compulsory retirement for the upper ranks. The view that it would be productive of hardship on medical officers to be compelled to go at sixty years of age seems to us an unreasonable and untenable one. The officers in the administrative ranks of that age will have long been not only in the enjoyment of a higher rate of pay and allowances, but they will have been on full pay service for years after the compulsory retirement of their juniors in the executive ranks, and when they do retire it is with a much higher rate of pay. Let the position of an officer who has had the good luck to have been promoted early and to have filled, it may be, the principal post in India, be contrasted with that of an executive officer going at fifty-five years of age, and the difference is enormously in favour of the former, especially when it is considered that there was, perhaps, little or no difference in the abilities, character, or services of the two men. The benefit of the Service, as a whole, should be taken, in this as in all other instances, as the true and legitimate basis of action; and if it be held right to compel a military chaplain to retire at sixty it certainly cannot be wrong to apply the same rule to a military doctor. If, however, Mr. Gathorne Hardy has another and better method for securing a reasonable flow of promotion we shall be very happy to hear it. And in any case we anxiously await the time when Mr. Hardy shall disclose his intentions, for the present condition of things is eminently unsatisfactory. We learn that at the last competitive examination twenty-two candidates went up, one retired, and the remainder qualified, out of whom fifteen were selected. From this it appears clear that Mr. Gathorne Hardy's statements as regards his intentions are considered to portend some changes for the better. We can only hope that the Service will not be disappointed.

THE PHARMACEUTICAL CONFERENCE.

THE twelfth annual meeting of the British Pharmaceutical Conference, held at Bristol, seems to have been a useful and creditable one. The address of the President, Mr. Groves, was interesting and well sustained throughout. It showed an admirable knowledge of the progress of pharmacy, and especially of the points of it at which scientific and practical ends meet. The President seems dissatisfied with the Irish Pharmacy Bill, and especially with the fact that it was framed without consultation with the Pharmaceutical Society. The withdrawal of the reciprocity clause was boasted of by one of the subsequent speakers as a result of the plain speaking of a deputation of the Council of the Pharmaceutical Society to the members of the House of Commons in the lobby. It is, to say the least, lamentable at this time of day that there should not be reciprocity between the druggists of England and Ireland, as there is between the doctors of the two countries. The President discussed the pharmaceutical position of some new or recent remedies, especially of jaborandi and salicylic acid. He referred with gratification to the production of salicylic and carbolic acids from the essential oil of a variety of the genus *Andromeda*, which grows inexhaustibly on the Neilgherry Hills. His account of the chaotic state of our knowledge of the active principle of digitalis makes us very thankful that there is a Pharmaceutical Society to take cognisance of such matters and present them in a practical form to medical men. The President was not slow to acknowledge the services of the profession in introducing drugs found useful in foreign countries, such as those of Dr. Fayrer in introducing Goa powder; and of Dr. Dougall, of the Indian Government, in employing gurjun balsam as a remedy for leprosy. Referring not very sanguinely to the prospect of an international Pharmacopœia, he expressed a hope that the indication of extreme doses would be made binding on the prescriber, as is the case now in Germany. This is only reasonable. We should all be grateful to a chemist for making inquiry in reference to the prescription of an obviously excessive quantity of a poisonous drug; and it is but due to dispensers to make such prescriptions clear, and not leave them in anxious doubt. We cordially endorse the views of the President as to the necessity for a commission which would grapple with the evil of the unrestricted sale of so-called patent medicines, many of which are frightfully injurious. He instanced one, known as the "sure cure for the opium habit," and found to contain two-grain doses of morphia, to be taken three times a day!

THE CASE OF GENERAL REECE, C.B.

THE letter of Mr. Low, which we publish to-day, if it puts the case in no new light, adds some important facts to the details which have already appeared. The history is a sad one. The final unhappy state of affairs appears to have been the result of family estrangement, which had lasted for many years, and to which the General's solitary life, and probably much of his mental state, are to be attributed. Whatever the General's actual mental condition may have been, it is to this estrangement that we must attribute any necessity there was for his detention and restraint as a certified lunatic. There is no account of violence which would have rendered it impossible for his friends to receive and take care of him. The law expressly favours the reception of lunatics by their relations, in its provision that any person deriving no profit from the charge may take care of a lunatic without legal supervision. The case was one, at the worst, of merely senile alienation, a condition apparently very similar to that of thousands whom no one dreams of incarcerating or restraining from the free exercise of their will, so far as such exercise is harmless to those around them. Whether or not the evidence of insanity was distinct and unquestionable we do not attempt to discuss. The point will, it appears, be decided before a legal tribunal, since the will of the deceased is to be disputed in the Probate Court. The letter of Dr. Tuke, which we published a fortnight ago, hardly explains the ground on which the certificates were signed, and he is in manifest error in believing that no medical opinion has been expressed in opposition to the affidavits which he and Dr. Maudsley signed.

While the circumstances of the case were such as to suggest the mildest mode of treatment, if any comfort to the patient or hope of recovery could be expected, there are sufficient evidences that the treatment adopted was one of considerable severity. The facts stated by Mr. Low, and, indeed, admitted by Dr. Tuke, show this clearly, as did also the evidence at the inquest. Not only was the old friend and banker denied admission, and only able to get access to General Reece at long intervals and by official interference, but even the landlady, who had been in constant intercourse with him, was not allowed to enter his room. It must be admitted that such treatment is likely to increase rather than lessen the mental disturbance of senile brain degeneration, and no facts have been stated on which it could be justified.

While we can hardly say with Dr. Tuke, that "the case shows very forcibly the intense jealousy of our English law of any undue interference with the liberty of the subject, and, with the present legal safeguards, the impossibility of any real sane man being treated as a lunatic," we are glad to believe that such cases as the present, in which even a doubt on the subject can arise, are of extreme rarity. The case illustrates, perhaps, the only danger of misapplication of our lunacy arrangements. It is not easy—it is, perhaps, not possible—for a man in perfect mental health to be confined as a lunatic. It is possible for a person of unsound mind to remain in the fullest possession of his liberty, to live unrestrained among his friends, provided he is not violent, and provided he has relatives willing and able to take charge of him. But it is possible for those who are on the borderland of insanity, who are in that condition in which some physicians may take one, and others another view of the exact mental state of the patient—the individuals whose harmless eccentricities are sometimes unreasonable but hardly mad, to whom freedom is happiness and restraint would be misery,—it is possible for these to be restrained and relegated to the mercies of a paid attendant, if the relatives are desirous that such should be the case. They have only to dismiss the doctors who consider the patient eccentric, and employ those who regard him as insane, and the thing is done. We do not say that this was so in the present case, but the circumstances show very clearly that it is possible, and that it is a loophole in our present lunacy system for the exercise of some practical injustice. It is probably not often that evil consequences actually ensue, but it would be well if means could be devised to prevent the occasion of such reflections as those which must arise from the circumstances of a case such as that of General Reece.

WOOD v. THE MANCHESTER, SHEFFIELD, AND LINCOLNSHIRE RAILWAY COMPANY.

IT would certainly have been by no means surprising had the juries to whose decision the practical issues of the case of "Wood *versus* the Manchester, Sheffield, and Lincolnshire Railway Company" were committed, failed to come to a uniform opinion on the merits of the case. To a lay mind the conflict of medical evidence must have been most perplexing. It is only by weighing carefully the character of the statements on the two sides that a fair judgment can be formed of the probable circumstances of the case, and even then the verdict can be only an approximative one. Our readers had, in the letter of Dr. Withington, which we published a fortnight ago, an account of the case from the point of view of the patient's medical advisers, in which it is contended that the cause of death was traumatic meningitis, consequent on an injury received in the railway accident. The letter of Mr. Dacre Fox, the medical officer to the Company, which we publish to-day, sums up the evidence in favour of regarding the cause of death as typhoid fever. The unfortunate man had been, on the one hand, exposed, certainly, to a possible cause of traumatic meningitis. On the other hand, he was possibly exposed to the cause of typhoid fever. The symptoms during life were compatible with either view. As to the post-mortem appearances, the most contradictory statements were made by the medical men who made or witnessed the post-mortem examination on the part of the friends of the deceased and of the Company. It is said by one side that the appearances of meningitis were amply sufficient to account for death; on the other, that the brain and its membranes were perfectly healthy. On all sides it is admitted that in the intestines there was a swollen condition of Peyer's patches, such as is seen in a certain stage of typhoid fever, but it is alleged by those who represented the friends that the appearances were not compatible with the condition which would be found on the seventeenth day of the disease, the day on which the deceased died; and, further, that they might be explained by powerful purgation at the commencement of the illness. The swollen condition of one or two of Peyer's patches is, indeed, the one positive fact which stands out among the conflicting statements concerning the post-mortem appearances. In accepting it as conclusive of the existence of typhoid fever, one fact is assumed for which there is no published corroboration—that typhoid fever may last sixteen days before the commencement of ulceration. The latest date on which ulceration has not been found has hitherto been the twelfth day. It usually occurs some days earlier, even in mild cases. Dr. Murchison, however, does not consider, as his statement to the Company shows, that the absence of ulceration at that date is exclusive of typhoid fever. The grounds on which his opinion is based — an opinion with difficulty reconcilable with the published statements in the last edition of his book—would be interesting to the profession. As it stands, it is the most authoritative opinion that can be obtained on the subject. If the merely swollen state of Peyer's patches of the intestines was not incompatible with typhoid fever, they might reasonably be supposed to be indicative of it—the symptoms during life being taken into consideration,—provided no evidence of meningitis was to be discovered. Here the conflict of statements, as it stands in the report of the inquest, is absolute. They can, indeed, only be valued by looking at the character of the assertions by which the several statements were supported. When we do this we must confess that the balance of knowledge of pathological appearances appears to be on the side of the Company. It is certain that the written opinion of Dr. Lancaster on the point, which was not, however, given at the inquest, has a special value, because, as former assistant at the West Riding Asylum, he must have been perfectly familiar with the appearances of the normal and abnormal meninges, and his opinion is "that there was nothing particularly abnormal in the brain or its membranes except some opacity of the arachnoid membrane." This is, we need not say, a most common condition apart from any preceding inflammation, as several witnesses on the side of the Railway Company pointed out. On the other hand, Dr. Morris, who made the post-mortem examination, asserted that the arachnoid was "rough, covered with lymph, milky white or semi-opaque." Much would depend upon the position of the roughness, and the value of this witness's evidence against the Company is reduced by his subsequent statement that the deceased was suffering from typhoid fever at the time of his death, although the death was due to meningitis—an opinion which, although not very satisfactory as a scientific explanation of the case, probably coincides very closely with the impression which the evidence would leave upon the mind of the jury, and with the verdict which they brought in.

The extreme practical inconvenience of the word "typhoid," as applied to the specific fever, appears very clearly from the report of the inquest. We find one medical witness asserting that the disease in the intestine showed there was typhoid fever, but that typhoid fever might result from the blood-poisoning with urea consequent on the retention of urine. If we find such confusion existing in a medical mind on the subject of typhoid fever and the typhoid state—a confusion which results from the unfortunate nomenclature which, in spite of the College of Physicians, remains, and seems likely to remain, the popular terminology —we cannot wonder that the task of witnesses and of juries in such a case is rendered even more difficult than the facts necessitate.

UNQUALIFIED OBSTETRIC PRACTICE.

THE death of Eliza Swain, from hæmorrhage, near the time of her confinement, undelivered, has been the occasion of an inquest at Islington. First a midwife was called, and then Mr. Byers. Mr. Byers, we have reason to remember, is unqualified. Mr. Byers went for another doctor, and found Mr. H. F. Burnes at 2 o'clock in the morning. When they returned the poor woman was dead. The midwife saw the patient in the preceding afternoon at 4 o'clock and again at 6, at which times there were no symptoms of hæmorrhage according to report. Of course it is possible in such cases for there to be great internal hæmorrhage without any or any proportionate appearance of blood externally, and it is to be admitted that such cases are amongst the most terrible in practice, even to the most accomplished accoucheurs. Schroeder says that the prognosis for the mother in such cases is much more unfavourable than in placenta prævia. Dr. Barnes says, "Death may occur in a few hours, even before delivery." Still there is much to be done in these cases which does not seem to have been done. The jury came to the following verdict:—"That death resulted from excessive hæmorrhage during labour, and that death was accelerated by neglect and want of proper skilled treatment on the part of an unqualified practitioner."

Mr. Burnes stated that on making a post-mortem he found a breech presentation, and no attempt had been made to deal with the case scientifically. The hæmorrhage which had taken place was dreadful. He had no doubt that if he or another qualified medical man had been called in earlier the deceased's life might have been saved. The placenta was not prævial. It is important to place the blame of these lamentable obstetric cases rightly. Our contemporaries, in reporting this case, give prominence to the fact that Byers is unqualified; but they ought to give prominence to the further fact that such is the disgraceful condition of the law that qualification is not required for midwifery practice. Anybody may practise midwifery. Byers has already been punished for using titles falsely. This he has ceased to do, and he breaks no law in attending lying-in women, whose cases, however, it is seen are often the gravest in practice. Our lay contemporaries should use their influence to procure a change in the law that permits unqualified persons, men or women, to practise midwifery. Until this change is made a great many lives will continue to be lost.

THE DISCUSSION ON VIVISECTION AT EDINBURGH.

CONSIDERING the importance of the subject of vivisection, and the way in which certain classes in this country especially have been moved by it, we think that it may be well to supplement Dr. Rutherford's remarks thereon, at the late meeting of the British Medical Association, by a reference to those made by Dr. Burdon-Sanderson and Sir R. Christison on the same subject. Dr. Burdon-Sanderson drew particular attention to the statement made by Dr. Rutherford—viz., that in the experiments used in illustrating the processes of physiology for teaching purposes, it was possible to demonstrate all the great facts, especially those fundamental facts which had made the last twenty years so notable in the history of the science, in animals altogether free from suffering. As regarded the result of Dr. Rutherford's own experiments, it was by means of such investigations alone that they could obtain an answer to the question, which, of all others interested them most in physiology, or, in fact, in any of the applications of science to medicine. The question was, How did those agents, of which they had a vague knowledge by means of their experience in medicine, affect the great functions of the body? They must all feel that it was of immense importance that the agents which they were using daily in practice should be known to them, not merely by the knowledge they gained from experience, but also by that kind of knowledge which could only be obtained by the application of scientific methods of investigation. In the instance before them there could be no doubt that the knowledge gained by Dr. Rutherford was of the most important and valuable kind, and the only question was whether the requisite skill and judgment were used in the performance of the experiments, in order to ensure that the best results were obtained, and that for every grain of suffering which was inflicted on the animals there might be got an equivalent of valuable knowledge. Dr. Burdon-Sanderson expressed his great confidence in the Legislature in this matter, and he believed that those who were considering the subject would not only be guided by motives of humanity, but afford evidence of a sagacious consideration of the necessities and requirements of the case. Sir R. Christison dwelt, and very forcibly, on the great practical value of the results obtained by Orfila and Majendie by the aid of animal experimentation, and adverted to some of his own labours and observations in toxicological science. Sir R. Christison did not suppose that anyone would desire to prevent our having recourse to such experiments as might either establish the guilt of a criminal or save a man's life when unjustly charged. Alluding to an investigation which he had undertaken to settle a very difficult and primary question as to the action of medicines and poisons through the medium of the blood or of the nervous system, Sir Robert said he had abandoned the method he had devised some time ago for settling the point, in consequence of the cruel nature of the experiments required; from which it might be inferred that in a great school such as that of Edinburgh, where men of sense knew what they should or should not undertake, nothing would be done in the least degree offensive to public decency or public opinion even; and, further, that cruelty was just as disagreeable to a vivisectionist as it was to any of those super-delicate people who were offering a reward of twenty guineas for the discovery of a vivisectionist.

THE CASE OF LOUISE LATEAU.

FOR the past seven years the public mind in Belgium has been greatly exercised by the performances of a country girl, who has been subject to weekly attacks of ecstasy accompanied by cutaneous hæmorrhages from special regions, which, from their associations, are held in Catholic countries in profound reverence. Many have been the pilgrimages to the village of Bois d'Haine, where this lowly mystic dwells, and many have been the treatises, religious and scientific, that have been written to explain the phenomenon from their special point of view. At the commencement of the present year a commission of the Royal Academy of Belgium, under the leadership of M. Warlomont, investigated and reported fully upon the case. The report, which was a most elaborate one, came to the conclusion that the girl was the subject of "stigmatic neuropathy"—a new addition to nosology. We have just received a most interesting memoir (*Science et Miracle: Louise Lateau, ou la Stigmatisée Belge*), by Dr. Bourneville, of Paris, the talented editor of M. Charcot's work on Nervous Diseases, and himself no mean contributor to the literature of neuropathy, in which, after careful study and analysis of the writings on Louise Lateau, he concludes that her case is nothing but one of extreme hysteria. After giving a detailed account of her early life, and of her manifestations, each of which—the stigmata, the ecstasies, visions, prolonged abstinence, anuria, insomnia, &c.—he analyses in full, he passes on to compare her case with those of other well-marked examples of hysteria, many of which either have been or are in the wards of La Salpétrière Hospital. A case is given in which cutaneous hæmorrhages, preceded by neuralgic pains, and occurring in different parts of the body, were met with, accompanied by hystero-epileptic fits. Another, recorded by Magnus Huss, of Stockholm, as early as 1851, in which the subject had similar hæmorrhages, unaccompanied by menstrual derangement, and without any hæmophilic tendency. This patient could even provoke the hæmorrhages at will, and became the object of much curiosity and sympathy. She also was subject to epileptiform attacks. With regard to the ecstasies, there has been in La Salpétrière since 1840 a most unique case of hystero-epilepsy, in which the convulsions are most extreme, and on several occasions the subject of them has passed into a state of cataleptic rigidity in the attitude of the crucifixion. Whilst in this state she sees visions of the Saviour and the Virgin, and in every respect, save the regularity of recurrence, the attacks resemble those of Louise Lateau. Prolonged abstinence, diminution or even suppression of the excretions, have also been observed among other subjects of hysteria, which even excel the mystic of Bois d'Haine in the extremity to which their functions are deranged.

A striking commentary regarding Lateau has just been going the round of the papers. "It appears that for some weeks, her sister having kept priests and sightseers aloof, she reverted to normal habits and conditions; but, relapsing into a state which led to priestly services being called in, the former symptoms—fasting, trances, and stigmata—have reappeared." *Verbum sat.*

GOVERNMENT RESEARCHES.

It is encouraging to find the time which must now elapse before the shortcomings of the last session in the matter of sanitary reform can be compensated, is not to be unimproved. Mr. Sclater-Booth has, it appears, determined to send out a commission composed of Mr. C. S. Read, M.P., Mr. Robert Rawlinson, C.B., and Mr. S. C. Smith, C.E.—the name of the scientific medical man who will, *of course*, be included in the staff has not transpired—to examine and report upon the various methods of disposing of town sewage adopted on the Continent. It is said that the inquiry will be directed "principally to the effects of frost, during severe winters, on closets, house-drains, and irrigated grounds." We should have supposed this might form a subordinate feature of the researches prosecuted. It surely cannot be difficult to conjecture pretty accurately what effects are likely to be produced by frost upon sewage. We presume it is in contemplation to separate the "storm-water"—i.e., the accumulated rain and washings of the streets—from the ordinary fluid of the sewage and domestic "slops." This procedure was, many years ago, held to be the first step essential in any efficient reform. Without doubt it would greatly facilitate the disposal of sewage if the superfluous bulk of the water could be separated from it. But there are sanitary perils in the way. It would never do to leave the house-drains without frequent flushing. We venture to suggest that the commission shall be further charged to inquire what effect the drought of a severe summer may have upon the closets and house-drains. Again, is the problem of "utilising sewage" solved in several places on the Continent at that risk to health which must always be entailed when sewage conduits and receptacles are left dry? We should be glad to hear that the atmosphere of some of the closets and air-chambers connected with the drains was to be examined and tested, that the effects of winds blowing through the sewers would be investigated, and that the general sanitary condition of the districts where sewage is "utilised" was to be carefully scrutinised and form a prominent topic of the official report.

DEAR MEAT.

What dear meat means already to householders is too well understood for them not to be gravely concerned with the unpromising prospect of having to pay still higher prices during the ensuing winter. In hospitals, also, where, of necessity, the consumption is large, the effect of high prices of meat will be greatly felt; and it will be felt even more severely in the case of sick people belonging to the poorer and middle classes, who have no funds to fall back upon. As it is, many belonging to the professional classes are much worse off and fare worse than the working classes in this country. As everyone knows, the consumption of meat has enormously increased of late years, and it forms the essential part in many households of three daily meals, to the injury very often of those who consume it. Still, in the case of sick people it sometimes happens that their diseases may be partly attributable to a state of chronic starvation, and it commonly happens that a liberal supply of animal food is required at some stage of their illness, or during convalescence. What with adulterations of many simple articles of diet, and the dearness of others, like milk, eggs, fish, and the like, many a professional man with a family outwardly maintains a fair social position, but, in reality, leads a life of what may be termed genteel starvation. The occurrence of a case of typhoid fever, or scarlatina, proves most disastrous in such a household, and may even irretrievably ruin the head of it. What dear meat means under circumstances like these can be more readily imagined than described. It is a question in which we are all interested, but we confess that while we have no sympathy with the grumbling of those—and they form a numerous class in this country—who eat more meat and do less work than is good for them, we cannot avoid sympathetically asking ourselves what is to become of people who are compelled to live with strict frugality, and, after toiling all day, are anxious at night as to the morrow's bills? Surely more extensive use might be made of Australian and other preserved meats imported into this country.

COMPOSITION OF PUS AND MODE OF FORMATION OF THE LEUCOCYTES OF PUS.

In a memoir recently presented to the Academy of Sciences, M. Bergeret, of St. Léger, gives the results of a long series of investigations he has undertaken in regard to the composition of pus, and the mode in which the leucocytes it contains are formed. He finds that every collection of pus, whatever may be its origin, contains pyocytes in three stages of development. 1. Young leucocytes not more than twenty-four hours old. These contain mobile corpuscles of various sizes and forms—globular, linear cylindrical, in chaplets, or dumb-bell-shaped, or hemispherical, and conceal the nuclei. The pus-corpuscles are highly hygrometric, and, when immersed in water, swell till they burst, discharging their granular contents and nuclei into the surrounding medium. 2. Young leucocytes from twenty-four hours to four days old. The nuclei of these are very apparent; a portion of their contents is still mobile, the remainder is attached to the nuclei and renders them granular. These leucocytes are smaller than the former, and irregular in form, in consequence of the envelope having contracted adhesions to the nuclei. They are less hygrometric, but still swell in water usually more or less irregularly; and the granules they contain, at first quiescent, soon begin to move, and escape when the envelope bursts. 3. Old leucocytes, the age of which is more than four days. These are small and crenulated, have lost their hygrometric properties, and their granules are no longer capable of reacquiring movement after imbibition of water.

In addition to the leucocytes, pus is also composed of serum, and in the serum float numerous mobile granulations of the same form as those contained in the interior of the leucocytes; their movements are, however, much more free, and whilst some may be observed merely to oscillate, others traverse the field of the microscope with more or less rapidity and in every direction. These granulations also, like those in the pus, only remain lively for about four days. After this they group themselves together, and form the small amorphous granular masses which are always met with in collections of pus, but especially in chronic abscesses.

M. Bergeret explains the formation of pus in a blister by pointing out that on the under surface of the detached epithelium there is a layer of amorphous mucus, which constitutes a pyogenic medium. He is opposed to Virchow's views.

VEGETARIANISM A CURE FOR INTEMPERANCE.

A paper read before a section of the British Association last week may perhaps call attention anew to one of a tolerably comprehensive series of specifics recommended for the cure of intemperance. Unfortunately they partake too much of the nature of those "love potions" and "beauty powders" which beguiled the faith of our forefathers. The notion of making a person possessed with the passion for drink temperate by feeding him exclusively on vegetables is at first sight so amusing that it amply justifies the pleasantry about a forthcoming proposal to prescribe "intemperance as a cure for vegetarianism." Without doubt the consumer of huge quantities of succulent edibles or of food which promotes the absorption of a considerable amount of water when it is eaten, is not so likely to drink copiously between meals as an individual who feeds differently. In so far, therefore, as the propensity to drink is called forth by the sensation of thirst, which is seldom the case with the genuine drunkard, the vegetarian may be less prone to irregular and uncontrolled indulgence than the eater of meat. It is also possible that the vegetable feeder, living, as it were, an octave under the consumer of flesh, may not require the same amount of stimulant to recover him to his habitual tone when he falls below from exhaustion; and it is this need that usually incites to drink. Meat is a stimulating diet, and in excess it is well known to elevate the pitch of organic life to a point of high tension. The artificial stimulant required by the excessive meat-eater is alcohol; the sufficient stimulant of the man who lives wholly upon vegetables may possibly be milk! There is something in this, though we state it thus broadly. Nevertheless, to attempt the cure of a propensity for the excessive use of stimulants by changing the whole character of the diet is so startling and unscientific that it reads more like the nostrum of an enthusiast than the conception of a sober practitioner. It entirely ignores the peril of lowering the vital tone of a system already enfeebled by over-stimulation. We venture to hope no one will have recourse to the expedient, even by way of experiment, except under conditions well considered and abundantly secured from a peril neither imaginary nor of small proportions; and we venture to think few who have bestowed as much thought on the prescription as these precautions imply will put it in practice.

CONCENTRATED FILTH.

Take an apparatus ingeniously constructed to collect and keep back all the worst impurities of water, while it allows the fluid to percolate slowly through its strainer; continue to pass water for drinking purposes through the residuum accumulated until it runs out so discoloured as to attract the notice of persons drinking it; let the water you subject to this *purifying* process have been previously driven, with force enough to stir up all deposits, into a cistern the bottom and sides of which are thickly encrusted with slimy matters derived from the same source, the water having first lain for a considerable time exposed to sun, rain, and air, in one or more of the reservoirs provided by water companies for the purification of their supply, but generally regarded by the neighbourhood as convenient receptacles for dead cats, and rapidly developing into aquaria. Could any procedure not intentionally designed to ensure a subtly impure condition of our principal drinking fluid be more likely to produce that disagreeable and dangerous state of matters? The domestic filter gives the finishing touch to a process eminently unsanitary, and all because the apparatus employed to cleanse the water passed through it is not itself sufficiently clean to be innocuous. It is probable that some of the most deleterious foreign substances in water are not eliminated by the filter. If this be the case, the consumer takes them in a highly diluted form, and may escape with impunity. But whatever the filter detains is accumulated in a mass of slime and filth through which the water trickles gradually, doubtless dissolving much which it would otherwise not take up and becoming more or less poisoned by the putrefying matter through which it is wantonly set to gravitate. The facts are so simple and suggestive that they need no enforcement. Better leave the water unfiltered than pass it gratuitously through a bed of concentrated filth. The notion of cleaning a filter once in twelve months, or, as is the practice in some establishments, once in three years, when the apparatus itself requires removal, is so nasty that unless the fact were notorious it would be over-credulous to speak of it. The custom of leaving cisterns uncleaned until they become interesting to the naturalist, and allowing reservoirs to grow into manure pits, is probably too deeply rooted to be changed by anything short of a revolution in the interests of common sense and common decency.

HEALTH OF CUSTOMS OFFICERS.

Dr. Dickson, R.N., medical inspector of Her Majesty's Customs, contributes his annual chapter to the nineteenth report of the Commissioners of Customs. Nothing specially worthy of record appears to have occurred during the year. The out-door Customs establishment consisted of 923 men, 700 of whom were stationed in London and 223 at Gravesend. There were in the force during last year 534 cases of sickness, 148 of which were due to diseases of the respiratory organs, 84 to those of the organs of digestion, 9 of the urinary organs, 1 to periostitis, 46 to diseases of the skin and cellular tissue, and 66 to accidental injuries. Dr. Dickson says, "the same remarkable absence of zymotic disease, which has been commented on in former years, testifies to the fact that notwithstanding the vast number of vessels (some 12,000) on which these officers have been boarded for a greater or less length of time, the risk of their contracting or conveying infectious maladies is apparently infinitesimally small." These officers have, however, had fortunate escapes, for several vessels during the past year passed Gravesend and hauled into dock with contagious disease on board, among which the *Abbotsford* steamship was conspicuous, which, when examined by the officers of the Port Sanitary Authority in the Victoria Docks, was found to have no less than eight cases of small-pox on board. There is no doubt that the work of Customs officers afloat is often risky and by no means specially conducive to the maintenance of health.

POLICE RETURNS.

The Commissioner of Police of the Metropolis, in his annual report issued lately, and to which we have already had occasion to refer, states that during the past year 2773 persons suffering from accidents or other causes were taken by the police to hospitals. The gratifying announcement is made that there was a diminution in the number of drunk and disorderly persons in 1874. We hope the improvement will be continuous. Colonel Henderson complains of the difficulty of dealing with this class of persons. It is a duty in the execution of which the police are frequently maltreated and always annoyed, "especially as the fact of a person being drunk is always a matter of opinion in which the medical gentlemen who are called in are frequently as much at fault as the police themselves." "There is, in fact, no medical test for drunkenness," bewails the Commissioner. It must be admitted that among such a huge number of cases an occasional mistake appears to be inevitable. We are glad to find that the most ample authority is now given to officers in charge of stations to send for medical aid in every case in which there is the least ground for doubt. In the year such aid was afforded to 7611 persons, of whom 2319 were found in a state of insensibility. The fees paid to surgeons out of the police funds amounted to £2115 of which a small moiety only was recovered. A great decrease in the number of prostitutes apprehended was observable. The general health of the force was about the average of former years.

IN PERILS BY WASHERWOMEN.

IT cannot be said that the sort of cleanliness secured by a plentiful recourse to the services of washerwomen is wholly productive of health or happiness. Apart from the circumstance that the soapy sisterhood are prone—especially those who protest in capitals that they use no chemicals—to reduce the newest and strongest raiment to the condition of tinder, there is the alarming fact that, as a rule, they cast everybody's clothes into the same cauldron, immerse them in the same indescribable solutions, and hang them up to dry in the same artificial atmosphere and humid exhalation of muck. It is too horrible to think to what dreadful contingencies the linen we wear in closest contact with the highly absorptive skin is exposed in the process of purification. Professor Tyndall has not yet scared the public with some sensational demonstration of the constituent parts of a vapour such as that with which the ordinary washerwoman fumigates the clothes of her customers after laving them in an elixir into the nature of which science should not inquire too curiously. If any such intellectual treat is in store for us, let us hope it may be long deferred. Meanwhile something should be done to secure at least the minimum of mischief from a measure of cleanliness meant to be health-preserving. An inspection of laundries, and particularly the establishments of those nondescript persons who "take in washing," would do much to throw new and needful light on the perils by which we are incontinently beset. Overcrowding in the matter of living is bad enough. We are not sure whether crowding clothes of all orders and conditions of foulness into one "wash," and then crowding them, damp and dirt-attracting, into an atmosphere seething with vapourised filth, is not as much to be deprecated and more to be feared.

OUTBREAK OF SCARLET FEVER AT HUDDERSFIELD.

SCARLET FEVER has made its appearance at Huddersfield, and the medical officer of health, Dr. Bland, reports that up to the evening of the 18th instant there have been seventeen cases since the 7th of August. All the early cases were scholars in the Huddersfield Church Infant School. The sanitary condition of the school does not seem to have been quite perfect—the gratings communicating with the drains to carry off the surface water being choked up, the closets not over clean, and the ashpit containing a quantity of semi-liquid excreta. The school-building itself, however, is lofty and well-ventilated. Dr. Bland very properly drew the attention of the Sanitary Committee to the importance of preventing "not only those who are recovering, but also those who have come in contact with them, from mixing with others, and so spreading the disease." The Sanitary Committee at once proposed to close the school in question, fearing lest other children should become infected, and a request to do so was addressed to the managers of the school, who at first declined to accede, but afterwards consented to close the school for three days! The Vicar of Huddersfield has written a letter to the Sanitary Committee denying that the school premises were in the insanitary condition described by the medical officer of health, and protesting against the closure of the school. As to the sanitary condition of the school, or whether the disease originated there, or was brought to the school, we cannot decide without a personal inquiry into the facts of the case made on the spot, but we heartily approve the action of the Sanitary Committee in closing the school after the appearance of scarlet fever among a considerable number of the scholars. The first duty of the Sanitary Committee was to check the extension of the disease, and this could only be done by isolation of the centres where the disease had been most severe and the cases most numerous. There is not a shadow of doubt that, however originated, the Infant School was the focus of the disease, and the intercourse of so many children at this infected spot was a source of danger to the inhabitants, and a means of disseminating the disease through all parts of the town.

HEAT OF RAILWAY CARRIAGES.

ONE of the many discomforts incidental to travelling at this time of year is the intolerable heat of the railway carriages, and the railway companies seem to do their utmost to increase it. We entered a carriage at Charing-cross Station the other day. It had evidently been standing for some time in the sun, for the wood was almost too hot to touch. The roof was black and dull—the best possible surface for absorbing heat, and both windows were shut. It was like entering a baker's oven, and we fled precipitately to a third-class carriage, where the temperature was, at any rate, some degrees below blood heat. In some conditions of body it would be highly unsafe to travel in such a carriage, and when we consider the ease with which the evil might be lessened, we are amazed that even railway officials do nothing in the matter. A false roof a few inches above the true one, painted white, and permitting the free passage of air below, would make a wonderful difference, and would be an advantage both in summer and winter. If any contrivance could be added which should allow the windows to be opened without giving entry to a cloud of dust, railway carriages might become positively comfortable, and some of the longing for State management of railways averted.

CAPTAIN WEBB AFTER HIS CHANNEL FEAT.

WE have received the following interesting communication from Mr. Thomas Law Webb, M.R.C.S. and L.R.C.P. Lond., of Ironbridge, Salop:—

"A few facts relative to the physical condition of my brother, Captain Webb, on his leaving the water after swimming from Dover to Calais, will be of interest to the profession. He assures me that on landing he did not feel at all cold, but was as warm as when he started. He felt, however, fearfully tired and exhausted, and was very sleepy. He fell asleep several times as he was being driven to his hotel, though roused repeatedly by his cousin (Mr. G. H. Ward, who never left him throughout), who thought it best not to let him sleep until he had taken some nourishment. At the Hôtel de Paris, he went to bed, and drank some hot wine. Immediately on getting to bed, he took his own temperature with a thermometer with which I had provided him, and found it to be exactly 98° Fahr. He did not *count* his pulse, but *felt* it, and says it was 'slower than usual.' After five hours or so of sleep, he awoke feeling rather hot and feverish. He then took his temperature again, when it had risen to 101° Fahr. He says that his face was then flushed, and his skin hot and dry. He then slept again for some time, and on waking felt himself 'all right,' excepting a troublesome stiffness of the arms and legs, scarcely to be wondered at.

"Towards the termination of his swim he became nearly blind from the salt water. He denies that he was at any time delirious (as was stated in some of the newspapers), and Mr. Ward also says that he certainly was not so. Moreover, I think that his own careful temperature observations disprove this. He told me on Sunday last that his temperature, when taken the second time, was 101° Fahr.; and I find that my thermometer (which he has just returned to me) still registers precisely 101°. At present he is perfectly well in every respect—indeed, as well as ever he was; for we must not consider the abrasions on his neck caused by the salt water to be of any account. That he is apparently *not one whit the worse* is an immense relief and satisfaction to me, and a further proof of the perfection and soundness of his circulatory system and constitution generally."

THE GROUSE DISEASE.

A member of our staff writes:—"Reports from the Scottish moors this season have all the same tenour, 'Birds never were so scarce.' In fact so great is the dearth of game in some parts of Perthshire that shooting parties are already breaking up, and sportsmen are returning homewards. This is doubtless the result of the disease which has been so prevalent of late years, and which seemed to be the natural consequence of the enormous quantity of grouse bred in 1872, the moors at that time having been literally over-populated. Density of population amongst grouse, as amongst human beings, seems to have the effect of exposing the weaker birds to the ravages of epidemics, especially should a scarcity of food coincide with great increase in the numbers of the birds, as was the case in 1873. 'The survival of the fittest,' however, is a law which is applicable to birds as well as to men, and sportsmen may find some consolation in the fact that the birds shot this year have invariably been fine and healthy. I hear from one moor on which over 700 head of grouse have been killed that not a single diseased bird has been found. Those, therefore, who have sufficient self-denial to leave a fair number for breeding purposes may expect fine broods and large numbers next year."

ALCOHOL.

The comparative effects of the various members of the series of alcohols obtained by fermentation have been studied recently by MM. Dujardin-Beaumetz, and Audigé. They found that the toxic properties correspond closely to their atomic composition; the higher the figures which represent the atomic weight the greater is the toxic property. The latter varies also, it is to be observed, according to the manner in which they are administered, being greater when introduced by the stomach than when injected under the skin. The experimenters explain this by assuming that the dilution of the alcohol by a foreign substance increases its toxic properties; it would probably be a more correct assumption that there are some limits to the power of subcutaneous absorption of alcohol. The effects of the several alcohols presented little difference beyond that of intensity; they were practically the same. The chief lesions found on post-mortem examination were congestion &c. of the mucous membrane of the intestine, congestion of the lungs, and pulmonary apoplexy. The intestinal congestion was so intense in some parts of the small intestine as to have led to hæmorrhage, and this was found equally whether the alcohol had been administered by the skin or the stomach. On the other hand, curiously enough, the pulmonary changes were more frequent when the alcohol was given by the stomach.

WISE PRECAUTIONS.

The committee of the Children's Hospital at Birmingham are entering with admirable spirit into the very necessary precaution of separating cases of an infectious character from the general run of diseases. They are building new wards for fever, diphtheria, and croup, establishing quarantine wards, providing separate laundries and homes for nurses, so as to cut off every possibility of injurious communication with other parts of the establishment. The importance of these measures cannot be exaggerated, and we call attention to them with the view of lending what support we can to the movement, and with the further object of recommending the adoption of equally prudent reforms elsewhere. There can be no question that the condition of too many provincial hospitals is lamentable in the extreme. Under the plea of poverty some of these institutions perpetrate offences against the first laws of sanitary science which would call down the severest censure if committed by establishments not privileged as these are. It would be better to let the poor remain in their own homes at the mercy of their neighbours than to remove them to some of the hospitals started without sufficient resources or under management so defective in point of wit and zeal that they soon become worse than useless.

THE ARREST OF CARDIAC PALPITATION.

A correspondent of *L'Union Médicale* draws attention to the influence on palpitation of the heart of lowering the position of the head. The effect is said to be its almost instantaneous arrest. Whether the palpitation be from nervous disorder of action or from anæmia, if the head be so lowered by bending forward that a mechanical congestion of the upper half of the body results, the irregular action speedily ceases. This treatment, however effective for pure palpitation, can hardly be recommended in cases of organic disease of the heart in which dyspnœa is associated with the disturbed action. It will probably be found useful in the simpler cases. The writer (Dr. Lardier of Rambervilliers) speculates that the effect may be analogous to or identical with the retardation of the cardiac pulsation which occurs as one of the earliest symptoms of asphyxia, and which appears to be a consequence of the venous stasis in the upper part of the spinal cord. It may, he suggests, be due to the failure of arterial stimulation to the roots of the nerves which pass from the spinal cord to the sympathetic, and which have for their function, as von Bezold showed, the acceleration of the heart's action.

SUCCESS OF STUDENTS AT EPSOM COLLEGE.

At the last Matriculation Examination of the University of London many of the students of the Royal Medical College acquitted themselves creditably, and one, Mr. A. Cutfield, passed third in honours. At the subsequent First M.B. Examination we find in the list of successful candidates the names of no less than five Epsom students, Mr. F. Baylis, Mr. E. M. Cuffe, and Mr. Noble (the last now a scholar of Keble College, Oxford—a scholarship gained in open competition), standing in the first class, and Mr. Thomas and Mr. Yate in the second. Considering that this is the first time that Epsom students in the ordinary course of their studies have been prepared for the higher examination, the result must be regarded as very satisfactory.

PARTRIDGE DISEASE.

ACCOUNTS we have received describe the partridge-shooting this year as unsatisfactory. In Surrey especially the birds are very scarce in low-lying parts, although on the high ground coveys of fair numbers and quality are to be found. Scores of young birds have died from an inflammatory affection which attacks the eyes, producing blindness, and so depriving them to a great extent of the power of obtaining food. The continuous wet weather which prevailed at the time when the birds were hatched may account for much of this loss. It would be interesting to ascertain the precise nature of the disease by careful examination of a few dead birds. The result would reward the pathologist, and might prove valuable in more ways than one.

MORTUARIES.

THE want of mortuaries in the metropolis is so frequently made apparent in inquest proceedings that we welcome any attempt to increase a very necessary provision. We understand that Dr. Joseph Rogers will shortly submit the following motion to the consideration of the Strand Board of Works:—"That, with the view to the more effectually and economically securing the establishment of mortuaries in the different parishes of the metropolis, this Board do memorialise the Metropolitan Board of Works, urging that Board to apply for powers in the next session of Parliament authorising that body to undertake their erection in such parts of the metropolis as may be considered necessary."

STENCH ON THE SURREY CANAL.

WHY is there such an intolerable stench on the Surrey Canal at the point where the South Eastern Railway crosses it? We have known persons absolutely nauseated by it, and many close the windows as they approach the spot. Have the sanitary authorities overlooked this choice corner, or are there some technical difficulties which have prevented the nuisance from being swept away? Surely the powers of the new Public Health Act enable the medical officer of health to make very short work with the offenders.

THE Medical Officer of Health for St. George in the East, Dr. Rygate, has intimated to the district authorities that he will lay before the Metropolitan Board of Works at the next meeting an official representation concerning 291 houses in the parish, which by reason of want of light, air, ventilation, sanitary conveniences and other causes are unfit for human habitation, and require rearrangement or reconstruction. As might have been expected, such a resolution has proved distasteful to the vestry, who think they ought to have been consulted by their officer before he determined on such a step. We hope Dr. Rygate will disregard any factious opposition to his course of action. He has given an example of courage and independence which might well be followed by his colleagues in other metropolitan districts. It is impossible for medical officers of health to perform their duty as long as they are hampered by local influence.

IN London 1440 deaths were registered last week, including 1 from small pox, 22 from measles, 71 from scarlet fever, 10 from diphtheria, 53 from whooping-cough, 24 from different forms of fever, and 215 from diarrhœa. Different forms of violence caused 43 deaths. The Asylum District Fever and Small-pox Hospitals at Homerton and Stockwell contained 225 patients on the 28th ult., 180 of whom were under treatment for scarlet fever. Of foreign cities, Berlin, as usual, has the highest death rate—viz., 45 per thousand annually.

THE special report on the licensing laws in Liverpool, published in *The Times* of the 2nd inst., makes a particular reference to the surroundings of the Sailors' Home in that town, that must perforce remind all sanitarians of the necessity for an extension of the Contagious Diseases Acts to our mercantile marine towns in general, and to Liverpool in particular. It appears, too, that the work would in this instance be comparatively simple, as it would appear that the haunts of sailors' prostitutes in this port are well known. Houses of bad character are, according to the chief constable, "there so full of prostitutes, that a respectable person would not go in." Pending the adoption of the Contagious Diseases Act, we recommend all shipowners who have not a regular complement of seamen on their staff to take advantage of the 9th section of the Merchant Shipping Act of 1867, and have all suspicious hands medically examined before signing articles.

THE *Gentleman's Magazine* for this month contains an article by Mr. M'Cullagh Torrens, M.P., on Hospitals. He insists "that in proportion as hospitals are big they are bad; that, in proportion as they are far off, they fail; and that in proportion as they are crowded with an accumulated mass of disease they cease to be what they ought to be—refuges for the saving of life—and become pest-houses for the harbouring of death," and supports his contention by quoting the opinions of medical men in favour of treatment in small buildings. We shall next week devote greater space to the consideration of the article.

THE sanitary state of Camborne is, according to Mr. E. S. Angove, the medical officer of health for the district, far from satisfactory. There are a large number of nuisances which require to be removed; very many houses are without privy accommodation; the water-supply is defective; there are many open gutters which smell very offensively; while the drainage calls for immediate improvement. In spite of conditions militating so strongly against the preservation of public health, the death-rate is not so excessive in the district as might have been expected, a result no doubt due to compensating natural advantages.

WE are glad to find that the St. Pancras Vestry has resolved to take the initiative in removing some of the pest centres to which attention was recently directed in THE LANCET. One or two of the worst nests are to be cleared away under the new powers given by the Artisans' Dwellings Act, and the medical officer has been directed to inquire and report upon the general condition of the parish. It is much to be desired that the zeal evinced by this "local authority" may extend to the authorities of Kensington, Westminster, and Chelsea.

AT an inquiry held by Colonel Cox, the Local Government Board Inspector, relative to the proposed sewerage works at Aspull, near Wigan, the Commissioner stated there could be no question as to the desirability of providing an efficient system of sewerage for the township; the fact that last year the death-rate was 39·7 per 1000 showed, he remarked, even the necessity of such a provision more strongly than could any words of his.

WE gather from a recent report by Mr. S. W. North, medical officer of health for York, that scarlatina, though in a mild form, still exists in that city, in spite of the measures which have been adopted for its suppression. The governing authorities of schools in infected districts have been warned of the danger of receiving children from suspected houses, and this precaution, when exercised, will probably prove very efficacious.

WE have no doubt that a considerable impulse will be given to the temperance movement in this country by the fact that Her Majesty the Queen has lately consented to become a patroness of the Church of England Temperance Society, a society which does not necessarily insist on total abstinence from alcoholic liquors.

A SERIOUS outbreak of scarlatina is said to have occurred amongst the children in the married quarters at the School of Military Engineering. We hope shortly to ascertain some particulars regarding the epidemic.

WE understand that Sir Duncan Gibb has resigned the office of Physician to Westminster Hospital in consequence of the state of his health.

SIR JAMES ALDERSON, Knight, M.D., and Arthur Farre, M.D., have been appointed Physicians Extraordinary to Her Majesty.

SIR ROBERT CHRISTISON has been elected President of the British Association for the year 1876.

LUNACY.

THE last Report of the Commissioners in Lunacy (a brief statistical summary of which was given in THE LANCET of the 7th ult.) contains, as usual, a number of interesting facts relating to insanity. There is, of course, a large actual and comparative increase in the total number of persons under confinement or supervision. The county and borough asylums appear to be more and more crowded with harmless and chronic cases, which, according to the opinion of the Commissioners, might we well provided for in workhouse wards. But, if we remember rightly, it was decided long ago that lunatics or imbeciles ought not to be retained in workhouses, because no proper machinery existed for their safe keeping and accommodation. Hence the origin of the establishments at Leavesden and Caterham. It appears that in the large asylums the night watching is still very defective. Epileptic patients are found dead in bed, and suicides have occurred in the night. This is the third time that the Commissioners have specially alluded to these faults. They express in this report a strong opinion that the sick and dying demand continuous care and nursing during the night; that the epileptics should have assistance always at hand during their terrible seizures, and that all suicidal patients should receive strict personal supervision.

It appears that the boroughs of Portsmouth, Norwich, Bath, and Derby are still without asylums, and that the other boroughs mentioned in the last report as being similarly situated have not as yet taken any steps to comply with the provisions of the Lunacy Acts. Of the patients in local hospitals, the recoveries during the year were, as compared with the admissions, in the proportion of 45 per cent., or 5 per cent. higher than in the previous year. There are now 115 houses in England and Wales licensed for the reception of lunatics, which accommodate unitedly a total of 2293 males and 2638 females. In commenting upon the workhouse establishments, the arrangements made for epileptic cases at the Brownlow Hill Asylum, Liverpool, are severely censured. There are no closets or bath-rooms in connexion with the ward, and no special lavatory. The only court available for exercise is entirely flagged, and is used by the inmates of the surgical wards as well as by the imbeciles and epileptics. The same unsatisfactory condition of things still exists in the Nottingham Workhouse, although on two previous occasions the Commissioners have commented upon these defects. The day-rooms continue to be much overcrowded, the means of personal washing insufficient, and the means of bathing inadequate. Three prosecutions have occurred during the year, none of which call for special notice. The State Criminal Asylum at Broadmoor contained at the end of last year 509 inmates, of whom 402 were men and 107 women. No person certified to be insane whilst undergoing sentence of penal servitude has been sent to this asylum from Millbank since November last. Another asylum is contemplated for the lunatic convicts now accumulating in prison, and for such convicts as may hereafter become insane, but it is not proposed to transfer to the proposed asylum any of the convict class now confined at Broadmoor. The report as to the arrangements of this asylum are altogether very satisfactory, but the Commissioners recommend the appointment of a fourth medical officer, as the professional duties are very responsible, harassing, and hazardous.

The Hospital for Lunatic Soldiers at Netley contained 44 patients, but a want of comfort and cheerfulness is still observable in the day-room, and it is remarked that the frequent changes in the attendant staff are prejudicial to the inmates.

The Royal Naval Lunatic Hospital at Yarmouth accommodates an average of 190, and the Royal India Asylum at Ealing 119 inmates, as to both of which establishments favourable reports are made.

The seventeenth Annual Report of the General Board of Commissioners in Lunacy for Scotland shows that on the 1st of January, 1874, a total of 8069 lunatics existed in Scotland, 1455 of whom were maintained from private sources, 6563 by parochial rates, and 51 at the expense of the State. It is also estimated that nearly 2000 unreported insane are maintained by their friends in private dwellings, most of whom belong to the classes little removed from pauperism. So that the proportion of insane to population is as 228 per 100,000, the most striking feature shown being the great increase of patients detained in asylums; for gratuitous treatment in asylums is now obtained with greater ease, the institutions are more scattered over the country, and patients entering them do not require to be removed so far from home and friends. The chartered and Royal Asylums, which have been erected out of legacies and donations from charitable persons, take the place of district asylums in England and Wales. They are partially maintained also by profits derived from the care of wealthy patients, but it is much doubted whether this relief to ratepayers is desirable. A comparison of statistics shows that in Scotland the private insane are treated in public institutions to a much greater extent than is the case in England, there being in the former country a larger proportion of public establishments of a high character receiving private patients.

Correspondence.

"Audi alteram partem."

WOOD v. THE MANCHESTER, SHEFFIELD, AND LINCOLNSHIRE RAILWAY COMPANY.

To the Editor of THE LANCET.

SIR,—A letter, written by Mr. Withington, of Doncaster, and an annotation, which appeared in your issue of August 21st, are my excuse for troubling you with regard to the above. Moreover, it is due to myself, to those gentlemen who took part with me in the case, and to the Company whom I advise, that deductions from an *ex parte* statement should not remain unchallenged.

The facts of the case are briefly these. Mr. Wood, farmer, of Darfield, near Barnsley, was one of several persons injured in a collision at Conisboro' station on November 21st, 1874, caused by a light engine going at the speed of six or seven miles an hour running into a train standing in the station. On Nov. 30th I first saw Mr. Wood at his house with his medical attendant, Dr. Seaborne, of Wombwell. Mr. Wood had traces of a bruise on the left temple; his left wrist was swollen; there were marks of abrasion, nearly healed, about the left elbow; he complained of occasional headache, sleeplessness, and felt shaken. On Dec. 23rd I received a letter from Dr. Seaborne to the effect that his patient, being well, was willing to settle with the railway company. On Jan. 2nd, 1875, I received another letter from

Dr. Seaborne to say his patient had become very ill indeed, asking me to see him, and telling me that Mr. Lister, of Doncaster, had been called in. On January 6th, accompanied by Dr. Leech, I went to Wood's house, having previously advised Dr. Seaborne that I was coming (a fact hitherto unquestioned until Dr. Withington's letter). To our surprise, neither medical attendant nor consultant was present, and it was not until I met Dr. Seaborne upon a subsequent occasion that I became aware that he had misunderstood what I wrote. After waiting for Dr. Seaborne a short time, and finding that if he was sent for he could not arrive in time to meet us, having obtained permission from the family to see Wood, we went into his bed-room; he was lying in bed on his back, in a dreamy, partly delirious condition; he knew me, called me by name, shook hands with me and also with Dr. Leech. His temperature was 103·6°; his pulse 130, feeble, the beats being somewhat indistinct. His tongue had a brown streak down the centre, the edges red. He had slight sordes on his teeth. His pupils were moderately dilated, responded well to the action of light, and exhibited no symptom of intolerance of light. The abdomen was distended, there was much pain on pressure in the right iliac fossa, and there was an ill-defined rash on the lower part of the sides of the abdomen. His wife told us the excreta were voided involuntarily and had been for two days. He had subsultus tendinum. There was no complaint of headache or vomiting, though his wife said that these symptoms had been troublesome. We considered that the symptoms pointed to typhoid fever and not to cerebral mischief, and so I reported to the Railway Company. We were at that time utterly ignorant of the existence of typhoid fever in the vicinity of Wood's house. On January 10th Wood died.

On January 11th, about 10 P.M., a telegram arrived at my rooms to say a post-mortem examination would take place next day at 10 A.M. I went to Barnsley (Darfield is five miles off in the country) as early as I could, and hence was not there at the time fixed by Dr. Seaborne, of which I had such short notice. Fortunately Dr. Seaborne had waited a considerable time, and when I arrived merely the skull-cap and a small piece of the dura mater had been removed. Drs. Lancaster, Blackburne, Aitcheson of Barnsley, and myself watched the dissection of the brain and its membranes throughout, and failed to see any abnormal appearances beyond some congestion of the pia mater and choroid plexus and slight opacity of the arachnoid membrane. If Dr. Withington will refer to Gray's, or Quain's, or Wilson's "Anatomy," and read up "Glandulæ Pacchioni," he will find in my "important admission" simply a recognition of a very common well-known anatomical appearance, certainly very different from the lymph of recent meningitis. It will thus be seen that four medical men who watched intently the whole dissection of the brain coincided in the opinion that there were no signs of meningitis. It would appear from Dr. Withington's letter that I did not see sufficient of the examination of the brain to form any opinion about the existence of meningitis; as a matter of fact, however, I was present during the whole of the examination except the removal of the skull-cap and the raising up of a small portion (not over two inches square) of the dura mater. The gentlemen who conducted that part of the post-mortem adopted the somewhat remarkable plan of raising in the first place a piece of the dura mater close to the longitudinal sinus at the vertex. That he should find when he did this "strong bands of lymph," which he subsequently described as like catgut, is perhaps not so much to be wondered at, but I fail to see how these could indicate that the patient had died of acute meningitis. I may add that Dr. Aitcheson, who saw this piece of dura mater removed, is quite certain that the appearances observed were normal. Even if the report presented by the medical men acting for the family at the inquest be accepted, the appearances would hardly be compatible with death from acute meningitis, for no trace of pus or purulent lymph was described as being present. But, as above stated, four medical men who watched the post-mortem absolutely deny the existence of any lymph whatsoever, and of these one, Dr. Lancaster, was for five years assistant medical officer at the West Riding Lunatic Asylum, and thus had special opportunity of being acquainted with the normal and abnormal appearances of the brain, having during that time made numerous post-mortems in cerebral cases. I must add, in fairness to myself and friends, that at the beginning I suggested a common note-taker, and that we should go into the case together. This was at once refused and quashed by Mr. Lister and his colleagues. The rest of the post-mortem appearances were, in short, these: lungs slightly congested, old pleuritic adhesions most marked on left side; heart healthy; liver congested on anterior edge; kidneys congested; stomach, duodenum, and jejunum nothing abnormal; in the lower two or three feet of the ileum the solitary glands were enlarged; the mucous membrane generally was congested, and about seven or eight inches from the ileo-cæcal valve were three *enlarged, raised,* and *intensely congested* Peyer's patches; the spleen was enlarged, and the mesenteric glands increased in size.

I was very anxious indeed to preserve the diseased portions of the intestines, and wished that they should be at once sent, together with the spleen, to any pathologist of eminence; but the opposition to my doing so was so very strenuous I had to give in, remembering I had no *locus standi*, only being present by "courtesy."

Now, with regard to the probability of Wood having contracted typhoid fever, we have distinct proof—first, that in cottages within fifty yards of his house there were then cases of typhoid fever, and had been for some time previously, and that the epidemic existing then was the second in six months; secondly, that the sewage from the houses in which were typhoid cases drained into a tank situated between the well of the farm pump and the cottages; thirdly, that the tank was full of this sewage and overflowing; fourthly, that the water of the farm pump contained organic matter, so as to render it unfit, and was condemned by Dr. Sadler, the medical officer of health for the Barnsley district. Dr. Sadler distinctly gave it as his opinion that the contents of the tank which received the sewage from the cottages where typhoid fever existed found their way into the pump well. The pump from this well was situated within a few yards of the door of Wood's house, and it was acknowledged that the water was used for general purposes, though denied that it was used for drinking. The drinking water, it is asserted, was always drawn from a pump situated two hundred yards from the farmhouse, but it was shown that even this water contained so much organic matter that it was unfit for use; and the medical officer states that, though close to this well there was some refuse which he believed was ash-pit refuse, from which the impurities might be derived, and though there was a slight inclination in the strata from this last-named well to the tank, still, that when the tank was full, its contents might readily permeate into the well from which the drinking-water was drawn.

I shortly note to you as follows some of my reasons for advising the Railway Company to resist a claim for causing Wood's death:—1. That during life I recognised the symptoms of typhoid fever. 2. That in my opinion, and in that of three other medical men of acknowledged position who saw the post-mortem examination, the lesions observed were those of typhoid fever, and not of meningitis. 3. That when the Company submitted the whole evidence, which had been most minutely and carefully taken at an inquest lasting three days, to three such authorities as Dr. Murchison of London, Dr. Noble of Manchester, and Dr. Clifford Allbutt of Leeds, they all reported in no undecided terms that, from the evidence given, they were of opinion that Wood died of typhoid fever. In the face of these would the Railway Company have been justified in paying a heavy claim, based on the assumption that Wood had died through their neglect?

I wish, in conclusion, to allude to a few points specially raised in Dr. Withington's letter. With regard to the headache, it was not present on the 6th of January, the day I visited Wood; it was not constantly present until the time of his death. Mrs. Wood, in her evidence, stated that her husband knew her up to the time of his death. This is not compatible with a comatose state. Although Peyer's patches may be reddened and made more distinct by purgative medicine, it can hardly be believed that a sharp aperient given sixteen days before death, and an ordinary dose of calomel a few days subsequently, would produce the condition characteristic of typhoid fever described in the report of the post-mortem by a gentleman who gave evidence for the plaintiffs, as in the "early stages of ulceration." With regard to the fact that, though between fifteen and sixteen days elapsed between the first symptoms of disordered health and death, yet distinctive ulceration had not appeared, all I can say is, that though Dr. Mahomed views this as absolutely contraindicating typhoid fever, yet two physicians, Dr. Murchison and Dr. Allbutt, who have made typhoid fever a special study, do not coincide in this opinion.

I have enclosed you a copy of the shorthand notes taken at the inquest, and other papers in connexion with the case, and I submit that had the case been tried before Dr. Withington's ideal tribunal, "arbitration by competent judges," and not before a jury, the verdict would have been upon the other side.

I am, Sir, your obedient servant,

Manchester, August 25, 1875. R. Dacre Fox.

THE CASE OF GENERAL REECE, C.B.

To the Editor of The Lancet.

Sir,—My attention has been directed to the leader in your issue of the 14th inst., and Dr. Harrington Tuke's letter thereon in your paper of the 21st inst.

The question as to General Reece's sanity will, it appears, be tried in the Probate Court, his sons having determined to dispute his will. I presume Dr. Tuke was ignorant of this fact, or he would not have attempted to induce the public to prejudge the case. Suffice it for me to say that Drs. Wilks, Sillifant, and Langston are all satisfied the General was of sound disposing mind, and that five gentlemen, as fully competent as medical men generally are, who were present when the General instructed the solicitor to prepare the will, which unfortunately induced the sons to call in Dr. Tuke on the day it was executed, will all swear that General Reece was capable mentally of disposing of his estate. The case, however, opens up much more important ground to the public, and I cannot help thinking that had Dr. Tuke known all the facts he would not have expressed his opinion that "it shows very forcibly the intense jealousy of our English law of any undue influence with the liberty of the subject, and, with the present legal safeguards, proves the impossibility of any really sane man being wrongfully treated as a lunatic." On the contrary, the case, as you observe, "illustrates very forcibly the need for extreme caution in dealing with those supposed to be insane." I have known General Reece for twenty years. His married life was not happy, for very early he was separated from his wife, by whom his children were brought up. I have now before me a letter from the Rev. W. S. Reece, admitting I knew his father much more intimately and better than he did, and giving as a reason that he had seen little or nothing of him since he was seven years old. In March last I was sent for to see General Reece. I found him in apartments he had resided in for six years. He was very ill from bronchitis, and desired to make his will. He had repeatedly explained to me the manner in which he should leave his property, and had asked me to be his executor, but this I had declined. After several interviews, he wrote me he was better, and should postpone making his will until he could come to my office; but he had a severe relapse, and I then, with his solicitor, Mr. Pike (Merriman, Pike, and Merriman), attested his will. I forbear mentioning its provisions for obvious reasons, but as the General became worse, I repeatedly urged him to permit me to write to his two sons (his daughter was and is in Australia); he, however, refused, as he had a great dislike to his children knowing how he had bequeathed his property. Eventually I insisted he should let them know he was ill, and to this he assented, upon condition that they did not come to town. Subsequently I was allowed to summon them, but the General dreaded their coming, and more than once declared that he knew he should suffer in consequence. In a few days he sent for me, expressed great indignation and regret at the treatment to which he was subjected, as it confirmed his forebodings, and he determined to alter his will. Both sons were informed of this intention, and they agreed to an arrangement between themselves to divide equally, but the next day the younger one informed me that he should dispute the will, as he believed his father to be insane. I cautioned him that the result might be very disadvantageous to him pecuniarily, and his brother asked me to prepare a formal notice for his signature, intimating that if the attempt was persisted in he would not be bound by the agreement mutually entered into; and he further asked me, as he could not longer remain in town, to arrange for the removal of his father nearer to my office. On the 26th of June Dr. Broxholm was of opinion the General might be removed, but arrangements made for this purpose were frustrated by Lieutenant Reece having informed his father that he was to be taken to a lunatic asylum, and the latter then again expressed his determination to alter his will. Both Mr. Pike and I did all we could to combat this intention, and eventually the General removed his affairs from Mr. Pike, and placed them in the hands of another solicitor, by whom the new will was prepared, I, with four gentlemen, being present when the instructions were given, and on this occasion with the knowledge of Lieutenant Reece. I consented very reluctantly to act as executor, but declined to receive a legacy. This was on the 1st of July, and, by special appointment with the General, I called to see him on the 3rd of that month, when, to my great surprise, I was refused admission, and informed that Drs. Tuke and Broxholm had signed certificates of lunacy. The next day I, with Dr. Wilks, saw Dr. Broxholm, who stated that the proceedings had been taken with the authority of the Lunacy Commissioners, and he declined to allow Dr. Wilks or myself to see the General. I at once submitted a full statement of the case to the Commissioners, and in reply received from their secretary a letter as follows:—"Major-General Reece has been placed under the charge of John Wheeler, by order of his son, Lieutenant Reece. The Commissioners in Lunacy have no authority to order the detention of a private patient." I sent a copy of this to Dr. Broxholm, and again demanded admission to the General. This being refused, I consulted no less than six eminent Chancery and common-law counsel, all of whom declared the case unprecedented, and the only advice I could get was to bring an action for false imprisonment. This being obviously useless, I, at the suggestion of an eminent authority on lunacy law, applied for a writ of Habeas Corpus, and I believe Justice Denman would at once have granted one had a member of the General's family applied, but he directed a summons to be served upon Lieutenant Reece and John Wheeler, to show cause why the writ should not issue. This summons was heard before Baron Cleasby, who at once said I must have access, and I left the Chambers with the distinct understanding that this would be allowed; but it was again refused, and it was not until the 9th of July that I, in the presence of Drs. Wilks and Broxholm, saw the General. From this date until the 26th of July every device was resorted to by the sons to delay the proceedings and to prevent my seeing the General, and I did not again do so until that day, when Dr. Wilks was again present, and the General himself wrote a letter to the Judge, requesting the writ might issue, and this was accordingly done on the 28th of July. The return was that the General was insane and physically incapable of removal, but it was not until the 31st of July, although I had made repeated applications, I saw the certificates of lunacy; but Baron Cleasby, seeing the flaw in them, upon which you very properly comment, and which Dr. Tuke states arose from directions received from the Commissioners, at once declared they were no answer to the writ, and that, as regarded the state of the General's health physically, he would satisfy himself; and his lordship accordingly, with his physician and clerk, went the same day to the General's apartments. After an interview of twenty-five minutes I was called in and informed by Baron Cleasby that the General could not be removed, but that he was fully entitled to the free use of his will, and that I, his solicitor, and any friends must see him whenever we pleased; and his lordship added, "that if he did not then make a formal order, it was only because he felt sure his directions would be respected by all parties." On this occasion the General declared I had his full authority for all I had done, thanked me, and begged I would see him with the solicitor the next day, and in the presence of Baron Cleasby, and with his lordship's full assent, the General then signed an official document. Judge my surprise upon calling the next day to find that I and the solicitor were jointly refused admission to the General, although, after considerable difficulty, we were permitted to see him separately. He was then much distressed, and I have no doubt the repetition—after believing he was free—of the treatment to which he had for thirty-one days been subjected had a very prejudicial effect upon his health. He declared he should have no peace until his son and the keeper were committed for contempt, and begged me to go at once to Baron Cleasby. This I did, but, being Sunday, nothing effectual could be done, and upon returning to Huntingdon-street the solicitor, after much trouble, discovered the General was dead. I do not suppose Dr. Tuke has purposely misstated the facts, but he would lead the public to believe that upon my representation the Commissioners instituted an inquiry. I annex a copy of their last letter to me in reply to my request, after the General's death, that an inquiry might be instituted. Dr. Tuke says the imprisonment lasted twelve days. The number was thirty-two. He says that upon application "Judge's orders were freely made to give me access to the patient." The above facts speak for themselves. And he adds: "The action by the learned Judge proves how much importance he attached to the question, and the promptitude with which he would have acted if he had found it necessary;" whereas, as soon as the various obstacles thrown in the way were removed, the Judge did act, but, backed by Dr. Tuke's certificate, the son actually set the Judge at defiance. I have no doubt Dr. Tuke was imposed upon, but what would he have said if the General had made a will in favour of the persons with whom he had resided so many years, and then, in consequence of kindness shown him by his sons during his illness, he had altered it in their favour? Would Dr. Tuke have then said he was acting under "undue influence and suffering from senile imbecility?" I think he will, now that he knows the truth, regret that he signed the certificate so readily.

There are, of course, numerous other facts, but I have trespassed too much already upon your space. I will only add that I have placed all the circumstances before the Home Secretary with a view to an alteration being made in the existing law, under which, I have no hesitation in saying, any English man or woman can be locked up in his or her own house without the possibility of seeing anyone but those who have taken the proceedings or who have been selected to carry them out. I trust I have said sufficient to induce you to lend me your valuable aid to ensure an alteration in the law. I have no pecuniary interest in the case, and am acting solely as the friend and executor of the late General Reece.—I am, Sir, your obedient servant,

Parliament-street, London, August 25th, 1875. S. P. LOW.

THE WEBB TESTIMONIAL FUND.

To the Editor of THE LANCET.

SIR,—Captain Webb is the son of a medical man in this neighbourhood, who is highly respected for his remarkable integrity of character and strictly upright and honest dealing in his profession; his grandfather and uncle were also surgeons of high standing, practising extensively some years ago near Wellington, Salop, and his eldest brother has succeeded his father, who from a long and laborious practice is too much enfeebled to render any assistance.

I should be much pleased to see a fund raised by medical men, to acknowledge the unprecedented feat and undaunted bravery of the son of a professional brother, who has had a family of fourteen children, twelve of whom are living.

I enclose a P.O.O. for two guineas.

I am, Sir, yours truly,
EDWARD G. BARTLAM, F.R.C.S.

Brosley, Salop, August 30th, 1875.

⁂ We have much pleasure in inserting the above letter, and shall be most happy to receive subscriptions for the furtherance of this fund. Amounts already received:—Dr. J. G. Wakley, £2 2*s.*; Mr. John Tweedy, £2 2*s.*; Mr. E. G. Bartlam, £2 2*s.*; Mr. S. Potter, £2 2*s.*

IRELAND.

(*From our own Correspondent.*)

THE prospect of a good harvest is very general throughout this island, notwithstanding the occurrence of heavy rain in some parts of the country, the effects of which are considered injurious according to the local reports.

Foot and mouth disease has occurred in some parts of Ireland; it is hoped, however, that the extent of its ravages is not very considerable.

The loss of nearly fifty thousand sheep in Ireland last year by dogs certainly demands the attentive consideration of the authorities. Doubling the dog tax and the immediate destruction of the many mongrels, and other apparently ownerless dogs now at large in this island, appear more than ever necessary at the present time. We look on the preservation of our food supplies as a medical matter, concerning so intimately as it does the public health.

Apropos of the enlargement and rebuilding of Coombe Hospital, now rapidly approaching completion, thanks to the very important aid of Sir Arthur Guinness, Bart., we may mention that a grateful remembrance of the present Baronet's father, to whose munificence Dublin owes the restoring of St. Patrick's cathedral, in the shape of a very interesting statue by the late Mr. Foley, has just been placed on its handsome pedestal within the railing which surrounds the cathedral in Guinness-street, on the south side of the nave of the cathedral. We have just had the pleasure of inspecting this very admirable work of art, which is a faithful likeness, and which is peculiarly interesting as being, it is said, the last of the eminent artist's works which received his final touches.

At the last meeting of the Dublin Sanitary Association, a resolution of condolence with the family of the late Dr. D. T. T. Maunsell was unanimously adopted. A resolution was also unanimously adopted by the same body, expressive of the desirability for prompt action, by the local Sanitary Authorities of Dublin, under the Artisans and Labourers' Dwellings Improvement Act of 1875, in a city where those classes suffer, as they at present so much do, from the want of suitable dwellings.

Dublin, September 1st, 1875.

Obituary.

JAMES NANCE, F.R.C.S. ENG.

MR. NANCE, the only surviving son of the Rev. John Nance, D.D., rector of Hope and Old Romney, Kent, was born on 20th May, 1818. He was articled to Curtis and Son, of Dorking, in 1835; afterwards studied at University College; became M.R.C.S. Eng. and L.S.A. Lond. in 1840, and F.R.C.S.E. in 1864. He practised at Eccleshall, Staffordshire, for upwards of thirty years, and died there, on May 15th, from (1) coma and (2) irritative fever, after a fortnight's illness, aged fifty-six.

His estimable and honourable conduct gained him universal respect, while his generosity of character and kindness of heart made him many friends. His medical skill, care, and attention, were bestowed as freely on the poor as on the rich, and even more abundantly, very often in cases in which no remuneration was ever asked for or thought of.

His funeral took place at Eccleshall on May 20th, and was attended by a large number of the inhabitants of Eccleshall, together with representatives from the various clubs of which he was the medical officer, as well as by numerous friends, assembled from far and wide to show public testimony to his worth. His name will ever be treasured in the memory of his friends and in the gratitude of the poor.

JOHN THOMAS MERCER, M.B.

A YOUNG man has recently passed away, immolated at the shrine of his profession by diphtheria. Gentle, kind, and unobtrusive, he never made an enemy. To the poor his life was one continued benefaction. When they heard of his death they stood aghast in tearful groups of four or five, and each one had some past benefit to recount. His every neighbour felt that he had lost a friend, and his convalescent patients went to bed again, so great was the shock to them. It is not a little thing to make a mark like this at the age of thirty-six; yet it is a grateful tribute to the daily teachings of a well-spent life. Honour and uprightness in thought and action made him the repository of all confidence, social and material, which is rarely accorded to men of twice his age.

In his brief illness he was gentle and patient and thankful, but never hopeful of his recovery. Sir William Gull, to whom he was clinical clerk, put off his appointments that he might give his help and sympathy to a professional brother, but all availed not. He passed away like a sleeping infant, without a struggle or a sigh. Such was the end of John Thomas Mercer, M.B., on June 9th, 1875. He was interred in Norwood Cemetery, and followed by the whole of the profession in the neighbourhood.

HENRY ASHTON, L.R.C.P. EDIN.

Mr. Ashton was born on the 5th March, 1813, at Slaithwaite, Yorkshire, received his early education under the Rev. P. Steel Dale, of Heallin's Green, Cheshire, and his medical education at Manchester. In consequence of bad health, he did not obtain the L.S.A. Lond. till 1847, when he commenced practice at Ramsbottom, where he speedily obtained a good connexion; but, not liking the neighbourhood, removed to Walton le Dale in 1849, where he remained until his death on the 11th May, at the age of sixty-two. In 1859 he passed the necessary examination, and obtained the L.R.C.P. Ed., and in 1860 was unanimously elected an honorary corresponding fellow of the Edinburgh Obstetrical Society, on the nomination of the late Sir J. Y. Simpson. He was an occasional contributor to The Lancet and other medical journals, and also to the provincial press on social and sanitary matters.

Mr. Ashton was a man of great energy, and untiring in the practice of his profession, making each case a separate study, and, though somewhat brusque in manner, had a singular faculty for obtaining the confidence of his patients, which he rarely afterwards lost.

JOHN McDERMOTT, M.D.

Dr. John McDermott, son of Edmund McDermott, Esq., of Cherryfield, County Roscommon, was born on the 21st June, 1796. He studied at the school of the Royal College of Surgeons, Ireland, became M.R.C.S. Eng. in 1824, L.R.C.P. in 1846, and M.D. of the University of Glasgow in 1847. He entered the Royal Navy as Assistant-surgeon 30th December, 1825; became Acting Surgeon of H.M.S. *Sparrowhawk*, 4th of July, 1834; served on the Home Station, West Indies, and South America; was invalided from the last station in April, 1836, and subsequently quitted the service. He settled first at Tacna, in Peru, where he had an extensive practice, and afterwards at Santiago, in Chili, where he met with great success, and won the esteem and gratitude of the community. Failing health compelled his return to England in 1863, and his retirement from the exercise of his profession. He died at his residence Shrewsbury-road, Westbourne-park, on the 10th May, from senile decay, aged 78.

G. CANNEY, M.D., F.R.C.S.

We have to record the death of Dr. George Canney, which took place at his residence, High Bondgate, Bishop Auckland, a short time since from apoplexy. Deceased, who was in his fifty-sixth year, was a native of Bishop Auckland, and was the only surviving son of the late George Canney, M.D. He took his degree at University College, London, at the hospital of which he was for some time house-surgeon. He was physician to the late Dr. Maltby, Bishop of Durham, as also to Bishops Longley and Villiers. Deceased held a high position as a physician in the North of England, and during the thirty-five years he resided in Bishop Auckland had an extensive practice. He was a liberal supporter of the Mechanics' and other institutions calculated to benefit his town. The intelligence of his sudden death evoked a feeling of sorrow in the town and neighbourhood. In politics the deceased was a staunch Conservative.

CHARLES T. HUSTON, L.R.C.S.I.

Mr. Charles Todd Huston was born in the year 1823, educated at Dublin, and became a Licentiate of the Royal College of Surgeons, Ireland, in 1848. On the resignation of his father in the year 1853 he was appointed medical officer of the Tynan Dispensary district in the Armagh Union, which appointment he held up to the time of his death, which took place at Tynan on the 11th May, at the age of fifty-one. By his demise the poor have lost an attentive, kind, and generous attendant, and his numerous private patients a skilful physician and a true friend.

Medical News.

Apothecaries' Hall. — The following gentlemen passed their examination in the Science and Practice of Medicine and received certificates to practise on Aug. 26th:—

Dobbie, Robt. John Algernon, Budleigh Salterton.
Laird, John, Palace-street, Pimlico.
Lewis, Edwin Alaric, Loraine-road, Holloway.
Oldham, Samuel, Burslem, Staffordshire.
Sargent, Arthur Francis, Lancaster-place, Belsize.
Upton, Alfred, Petworth, Sussex.
Worswick, Fredk. Henry, Hulme, Manchester.

The following gentlemen passed the Primary Professional Examination on the same day:—

Robert Kendray Archer, Westminster Hospital; William Laird Cox, St. Mary's Hospital; William George Creswell, Queen's Hospital, Birmingham.

At the recent examination for the Prizes in Materia Medica and Pharmaceutical Chemistry the successful candidates were:—

1st.—Frederick Freer Leslie Robertson, St. Bartholomew's Hospital. The Gold Medal.
2nd.—Neville Scott Whitney, University College. The Silver Medal and a Book.

The library of the Obstetrical Society will be closed from September 6th to September 18th, both days inclusive.

Pharmaceutical Society of Ireland.—The following constitute the first Council of this Society:—President: Sir Dominic Corrigan. Vice-President: Aquilla Smith. Council: William Henry F. Allen, M. V. Bourke, Thomas Collins, Dominic Corrigan, William Frazer, J. Goodwin, William Goulding, William Harrington, William Hayes, John Hodges, E. M. Hodgson, J. Holmes, R. W. King, C. H. Leet, Rawdon Macnamara, J. B. Owens, J. E. Reynolds, John Ryan, Aquilla Smith, C. R. C. Tichborne, and H. Whittaker.

Donations &c., to Medical Charities.—Sir John Arnott has executed a deed of gift, vesting the sum of £20,000 in trustees for the benefit of charitable institutions in Cork. About £9000 has already been subscribed out of the £15,000 required for the new Clayton Hospital and Wakefield General Dispensary. Mrs. Gibbs, of Tyntesfield, has endowed four beds at the Weston-super-Mare Sanatorium with £50 a year each, representing a capital of £5000 and upwards. The Sussex County Hospital, Brighton, has received £500 under the will of Mrs. Blegborough.

Medical Appointments.

Attwater, A. W., L.R.C.P.Ed., M.R.C.S.E., has been appointed Medical Officer of Health for the Wickham Urban Sanitary District.

Browne, J. W., B.A., M.D., M.R.C.S.E., has been appointed a Surgeon to the Belfast Royal Hospital, vice Dr. S. Browne, R.N., J.P., Senior Surgeon, resigned.

Browne, S., M.D., M.R.C.S.E., J.P., has been appointed Consulting Surgeon to the Belfast Royal Hospital, after twenty-five years' service.

Croly, A., L.K.Q.C.P.I., L.M., L.R.C.S.I., has been appointed Medical Officer, Public Vaccinator, and Registrar of Births &c., for the Glencullen Division of the Dundrum and Glencullen Dispensary District of the Rathdown Union, vice Sutton, resigned.

Davidson, C. M., M.R.C.S.E., L.M., has been appointed Medical Officer to the Lead Company's Workmen's Medical Union, Alston.

Evans, H., L.R.C.P.L., M.R.C.S.E., has been appointed House-Surgeon to the Croydon General Hospital, vice Ilott, resigned.

Faulkner, W. I., M.D., C.M., has been appointed House-Surgeon to the North Staffordshire Infirmary, Hartshill, vice Cox.

Gill, J. B., M.D., M.R.C.P.Ed, M.R.C.S.E., L.S.A., has been appointed Medical Officer of Health for the Sandgate Urban Sanitary District, vice Howard, resigned.

Griffiths, J. T., L.R.C.P.Ed., L.F.P. & S. Glas., has been appointed Medical Officer of Health for the Llandwrog Sub-district of the Carnarvon Rural Sanitary District, vice Williams, resigned.

Hart, W. H., M.B., C.M., has been appointed Medical Attendant to the Royal Irish Constabulary, Tullow, Co. Carlow, vice Burnett, deceased.

Hoar, C. E., M.B., L.R.C.P.L., has been appointed a Physician to the West Kent General Hospital, Maidstone.

James, C., M.R.C.S.E., L.S.A., has been appointed Medical Officer for No. 2 District of the Marlborough Union, vice Ryder, resigned.

Johnstone, C. R., L.S.A., has been appointed Assistant Medical Officer to the Haydock Lodge Retreat, Ashton, vice Anderson, appointed Senior Medical Officer to the West Derby Union Workhouse, Walton.

Leslie, E. J. L., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer to the Hampshire Friendly Society, Holybourne District.

Morgan, E. R., M.R.C.S.E., has been appointed Assistant-Surgeon to the 15th Glamorgan Volunteers.

O'Grady, W. F., L.R.C.S.I., L.M., has been appointed Junior Assistant Medical Officer to the Workhouse Infirmary, New Bridge-street, Manchester, vice Pountney, resigned.

Oldham, S., M.R.C.S.E., has been appointed Medical Officer and Public Vaccinator for the Norton District of the Leek Union, vice Goddard, resigned.

Renny, A. W., M.D., has been appointed House-Surgeon to the Stirling Royal Infirmary and Dispensary, vice Purves, whose appointment has expired.

Shand, J. W. F. S., M.D., L.R.C.S.Ed., has been appointed Professor of the Practice of Medicine in the University of Aberdeen, vice Mac Robin, resigned.

Shorland, E. P., M.R.C S.E., L.S.A., has been appointed Medical Officer and Public Vaccinator for No. 1 District and the Workhouse of the Westbury and Whorwellsdown Union, Wilts, vice G. Shorland, deceased.

Smith, J. P., L.R.C.P.Ed., L.R.C.S.Ed., L.M., has been appointed Resident House-Surgeon to the Loughborough Infirmary and Dispensary, vice Bailey, resigned.

Thomas, G. D. P., M.R.C.S.E., has been appointed Medical Officer of Health for the Willesden Urban Sanitary District.

Walter, W., B.A., M.B., L.M., L.K.Q.C.P.I., L.R.C.S.I., has been appointed House-Physician to the North Staffordshire Infirmary, Hartshill, vice Faulkner.

Births, Marriages, and Deaths.

BIRTHS.

Brown.—On the 26th ult., at Broadstairs, the wife of C. R. Brown, M.D., of Beckenham, prematurely, of a daughter.

Fisher.—On the 23rd ult., at Mellifont-avenue, Kingstown, the wife of J. W. Fisher, M.D., Staff Surgeon H.M.'s Ship "Vanguard," of a daughter.

Hopkins.—On the 30th ult., at Esbourn, Beckenham, the wife of Alfred B. Hopkins, M.R.C.S.E., of a son.

Lupton.—On the 13th ult., at Stratford-on-Avon, the wife of Harry Lupton, L.R.C.P.L., of a son.

Lynes.—On the 26th ult., at Priory-row, Coventry, the wife of Edward Lynes, M.D., of a son.

Marshall.—On the 24th ult., at Oak-bank, Lamberhurst, the wife of John J. Marshall, L.R.C.S.I., of a son.

MARRIAGES.

Davis—Lawson.—On the 26th ult., at St. Mary's Catholic Church, Norwood, John Norman Davis, M.D., Surgeon Army Medical Department, to Mary Emily Barron, daughter of the late John Lawson, Esq.

Kidd—Rouse.—On the 1st inst., at Balham, Joseph Kidd, M.D., to Frances Octavia, daughter of R. J. Rouse, Esq.

Pearce—Thackrah.—On the 31st ult., at Virginstow, Devon, Edward Thos. Pearce, L.R.C.P., of Holsworthy, to Mary Eden, only daughter of John Thackrah, Esq., and granddaughter of the late John Collins Browne, Solicitor, of Holsworthy.

DEATHS.

Ballenden.—On the 25th ult., at Sedgley, Staffordshire, J. H. Moffat Ballenden, M.R.C.S.E., aged 35.

Burrows.—On the 20th ult., at Normanton, Thos. Ash Burrows, L.S.A.L., aged 66.

Chilver.—On the 15th ult., at Upper Brunswick-place, Hove, Brighton, T. F. Chilver, F.R.C.S.E., aged 70.

Dillon.—On the 26th ult., at Waltham-terrace, Blackrock, Co. Dublin, Thos. Dillon, M.D.

Henry.—On the 27th ult. (at the residence of his brother, Emerson W. Henry M.D., C.M., Lowther-street, Whitehaven), George Henry, L.R.C.P.Ed., L.R.C.S.Ed., aged 29.

Mackeson.—On the 22nd ult., at Church-street, St. Peter, Brighton, H. S. Mackeson, M.R.C.S.E., aged 69.

Nunn.—On the 17th ult., at Portsea, R. M. Nunn, M.R.C.S.E., aged 73.

Notes, Short Comments, and Answers to Correspondents.

THE STUDENTS' NUMBER OF THE LANCET will be published on Saturday next, Sept. 11th. Those gentlemen holding official situations connected with Medical Institutions in the United Kingdom, who have not yet forwarded the necessary information to our Office for publication in that Number, are earnestly requested to send it *without the delay of a single post.*

Baby Farming at Uxbridge.

A recent inquest on the body of an illegitimate child disclosed the fact that a married woman, living at Hillingdon Heath, near Uxbridge, had recently had under her care two infant children of domestic servants, and Dr. Diplock, the coroner, ordered her to be prosecuted, under the Infant Life Protection Act, "for receiving for hire two infants under the age of one year for the purpose of nursing, apart from their parents, for a longer period than twenty-four hours, the house not being registered in accordance with the provisions of the Act." The case was heard on the 30th of August at the Uxbridge Petty Sessions, and the magistrates, in consideration of the fact that it was the first case of the kind which had been brought before them, dismissed the summons, with a warning to the defendant that if she again received infants to nurse, without registering her house, she would render herself liable to a fine of £5, or six months' imprisonment. It is much to be regretted that these cases of baby farming usually escape notice until their fatal results appear in the death register. This being the case, it is somewhat difficult to sympathise with the extreme leniency shown to the offender in the above-mentioned case. A conviction and the infliction even of a nominal fine would at any rate have served as a more useful warning to others who, almost in ignorance of the Infant Life Protection Act, may be rendering themselves liable to penalties under its clauses. The greater publicity that is given to such cases the greater is the probability of others being brought to light.

Dr. Mackay is thanked. It shall be published soon.

The Death under Chloroform at Quarry Bank.

To the Editor of The Lancet.

Sir,—I see in the last number of The Lancet that Mr. Ker, while abandoning several of his points of attack on Mr. Ashmead, still reiterates one or two others. Having assisted at the autopsy of M. Wyatt, I should like, with your permission, to make one or two remarks.

Mr. Ker's dictum in regard to the empty condition of the heart's cavities precluding death from suffocation does not accord altogether with the teachings of forensic medicine, where the law is not so rigidly laid down. The case of Carlo Ferrari, the Italian, who was first made intoxicated and afterwards suffocated, is an example of this kind, both sides of the heart being found empty. The action of chloroform appears to me to be likely to produce a similar effect, insensibility often taking place before respiration has been interfered with, and consequently lessening in a great degree the struggles of the patient. That the violet tint was not the result of post-mortem decomposition is reasonable, as nothing approaching it was visible on any other part of the body, though Mr. Ker says that "there could be no doubt about it." Mr. Ker was present at the examination of the lungs, and appeared to be satisfied that they were in a diseased condition. He did not, although laying so much stress upon it now, make any allusion to the hydrostatic test then, and I do not think it would have been mentioned had not Mr. Ashmead stated that the deceased was a bad subject for the administration of chloroform. Notwithstanding the authority quoted of the unnamed pathologist, I would remark that the hydrostatic test is not quite free from objection, as the lungs might have floated from the effects of decomposition and the generation of gas, and therefore would not of itself have proved that they contained air. Pathology has advanced sufficiently, I deem, to show without this test whether consolidation of the lungs existed or not. Air was not squeezed out, but pus was, on making numerous sections with the knife; the texture was denser, and the colour of the surface was not that of healthy lung.

The question was put before Mr. Ker left, whether any further examination of the abdomen was wished. It was, however, further examined when securing the stomach. Mr. Ker left before the post-mortem examination was finished, and before Dr. Walker arrived. Mr. Ashmead has already admitted that he overstated the amount of pus in the abdomen, which he most certainly did.

Mr. Ker attempted in his first letter to infer the post-mortem conditions from the diagnosis—an unusual method, and with which the medical referee is not concerned. The clinical history of the case does not, however, point to healthy lung.

In conclusion, I would remind Mr. Ker that if he had anything to allege against the correctness of the tests for chloroform, the inquest was the proper place to impugn such testimony.

I am, Sir, your obedient servant,
James Bradley, M.R.C.S.

Pensnett, near Dudley, Aug. 24th, 1875.

⁂ Here this controversy must end.—Ed. L.

Mr. A. Lloyd Jones.—Full information may be obtained by addressing a communication to the Under-Secretary of State for India, at the India Office. The address referred to was not published in the columns of The Lancet.

F. H. D.—We will endeavour to comply with our correspondent's request.

THE BOARDING-OUT OF ORPHAN PAUPER CHILDREN.

THIS system meets with unmeasured condemnation at the hands of Mr. E. C. Tufnell (long known as one of the inspectors of workhouse schools) in an article in *Macmillan's Magazine* on the Education of Pauper Children, whilst the system of district schools is correspondingly lauded. The writer advances three objections, which he terms "unanswerable," to the boarding-out plan:—First, that it simply takes notice of the best conditioned children—the orphans,—and wholly neglects the casuals, from whom alone the real difficulty of pauper education arises, and who are seriously injured by the removal of the best behaved. Secondly, that it sanctions what Lord Henniker calls "the iniquitous practice of non-resident relief. Thirdly, that it is opposed to the old principle of directly encouraging independence, industry, and thrift among the labouring class, and directly discouraging their opposites. We must refer to our number of Nov. 14th last year for our views on this question, merely repeating here that the favourable results of the system already made known—e. g., in Cumberland—fully warrant its more extended trial.

Mr. W. Berry is thanked for his letter.

A MEDICAL CORONER'S INQUEST.

To the Editor of THE LANCET.

SIR,—The letter published in THE LANCET of the 28th inst., headed "A Medical Coroner's Inquest," will, I earnestly hope, direct the attention of the profession to a grievance from which others besides Mr. Chatterton have suffered. I allude to the unjustifiable imputations which are too often thrown upon medical men by coroners' juries, and sometimes by coroners themselves, without the victims being able to obtain any redress.

If a tithe of what Mr. Chatterton says be true, can anyone doubt that he has been grievously wronged? A charge of malpraxis, which, if established, would result in a criminal prosecution, is as serious a matter for a medical man as a charge of forgery would be to a banker or anyone in a position of trust. But if anyone were rash enough to insinuate the latter on the same flimsy grounds that coroners' juries base the former, it is more than likely that smart damages in an action for libel would teach the accuser the value of reticence.

I apprehend that inquests exist for the purpose of ascertaining the cause of death, and to deliver an opinion as to whether such cause be natural, suicidal, homicidal, accidental, or the result of culpable carelessness. But without a post-mortem, how is it possible to ascertain the cause of death in such cases as the above. A verdict delivered upon such insufficient grounds is absolutely worthless, and any insinuation of malpraxis is simply impertinent.

Unfortunately in some parts of England—I speak from experience—the notion prevails amongst the class from which coroners' juries are chiefly drawn that an inquest is held for the purpose of *trying somebody for culpable carelessness* or crime of some sort; and if the relatives of the deceased (who, if not on the jury themselves, are sure to have friends amongst them) take into their wise heads to differ from the medical man concerned in the case as to the propriety of his conduct and treatment, it requires very little to persuade a country jury that the medical man deserves a criminal prosecution. Now, if such cases as Mr. Chatterton's were always to be followed by similar proceedings, our lives in benighted districts would become simply unbearable, and we should have to organise a general exodus—say to Central Africa, where I understand the native "medicine men" are treated in a less heathenish manner by their sable patients.

In conclusion, I beg to say that Mr. Chatterton and the coroner are alike total strangers to me.
I am, Sir, yours &c.,
Staunton, Gloucester, Aug. 31st, 1875. C. MOSS CAMPBELL, M.D.

MISPLACED BENEVOLENCE.

WE have received a letter from *Captain Brabazon*, "Hon. Secretary to the Central London Throat and Ear Hospital, Manchester-street, Gray's-inn-road," with reference to an article in our impression of the 21st ult. under the above heading. We must decline to enter into a controversy with a lay correspondent on a matter the merits of which can only be judged from a professional stand-point. We will only say that we see nothing in Captain Brabazon's letter to modify our opinion of small special institutions such as that whose claims he advocates.

Enquirens.—If our correspondent will write to Professor Humphry, Cambridge University, he will get the information he seeks. We believe there is an examination in October.

EXTRACTION OF A BOUGIE FROM THE FEMALE BLADDER.

To the Editor of THE LANCET.

SIR,—The following case may be of interest to some of your readers, such not frequently occurring in the practice of the same country surgeon.

Aug. 14th, 1875, 3 P.M. Mrs. ——, aged eighty. Thirty years ago she was supplied by two surgeons of repute, both since dead, with a male metal bougie to pass into her bladder from time to time, owing to occasional difficult micturition, which was attributed to a small fibrous tumour at the orifice of the urethra. She has used it since till it has worn and broken to 3½ inches in length. This she passed at 3 A.M., when it slipped into the bladder. She hoped it would pass back; hence the twelve hours' delay in requesting assistance. I passed a forceps into the bladder, and after a few attempts grasped the middle of the bougie. I then put my left forefinger into the vagina, and steadied it directly across the neck of the bladder. I then loosened the blades of the forceps, and carried my right hand to the right thigh, and tightened the blades, and carried my hand to the middle line. By repeating this manipulation three or four times I could feel nothing projecting beyond the forceps on the left side. I then succeeded without difficulty in extracting the leaden bougie, 3½ inches long, No. 8 size.

15th.—4 A.M.: Removed by catheter a pint of urine stained with blood, and gave twenty grains of chloral hydrate.—9 P.M.: Has slept, and passed urine comfortably, and of normal colour.

17th.—Convalescent.
Yours truly,
Framlingham, August, 1875. GEO. E. JEAFFRESON.

Dr. Tattersall, (Clayton.)—1. Our correspondent's qualifications and the fact of his having passed the preliminary examination in Arts at Apothecaries' Hall do not exempt him from being compelled to pass the matriculation examination and the other examinations required by the University of London to obtain the M.B. degree, unless his diploma dates prior to the year 1840, in which case he will be admitted to the 1st M.B. examination direct.—2. At least one year's residence is required by the Scotch Universities. Our correspondent's best plan would be to apply to them for information. Aberdeen would be suitable.—3. To obtain the F.R.C.S., he must pass the two examinations (primary and pass) required by the College. For further particulars, see the Students' Number of THE LANCET.

A Governor.—The rule seems explicit enough. A candidate must be F. or M.R.C.S. The governing body might, of course, frame a bye-law to meet such a case as that described.

ORGANISATION OF THE MEDICAL DEPARTMENT OF THE ARMY DURING WAR.

To the Editor of THE LANCET.

SIR,—With the Army Circular of August, 1875, the authorities have issued a pamphlet, showing the "war strength and composition" of the various components that will for the future go to make up an "army corps," as the new nomenclature of war designates what, at all events as far as England is concerned, is really an army complete in every essential.

With the purely military portion of the scheme THE LANCET has little to do, except to take a general glance at the strengths of the various atoms that unite to form the one harmonious whole; but the portion relating to the medical service of the army is specially interesting to all professional readers.

The pamphlet is drawn up as follows:—First, the exact composition of a regiment of infantry and cavalry is noted; then of batteries of artillery, with the reserves, engineer, pontoon, and telegraph trains. Next is detailed the ambulance equipment, with that of field hospitals; then follows the army service corps. The composition of a brigade of cavalry and infantry is then detailed; then that of a division; and, finally, an "army corps," complete in all its parts, is given *in extenso*. The total of an infantry regiment is put down at 1097 of all ranks, with one medical officer, who is also entered as being a mounted officer. A regiment of cavalry is to have a strength of 480 horses, with a total of 549 men of all ranks. One medical officer is also allotted, with two chargers. To each battery of artillery, and to each reserve, engineer, pontoon, and telegraph troop, a surgeon is detailed, and it is specially noted that each company of the army service corps is to be so composed "as to allow at once, upon entering upon active service, of division into two companies, so that it may be locally augmented with rank and file and horses, there being sufficient trained officers and non-commissioned officers in each company for the purpose."

The details of the medical department for a field hospital then follow. Each is to contain 200 beds, with the following staff:—Medical officers, 7; captain of orderlies, 1; men of army hospital corps, 37; drivers, 12—total, 49. Hospital waggons, 4; surgery waggons, 2—total, 6; with 24 horses. The medical officers are to be detailed thus—1 medical officer in charge, 2 senior surgeons, 4 surgeons. With each cavalry brigade, consisting of three regiments of cavalry and a battery of Royal Horse Artillery and staff—in all, 2139 men,—1 field hospital will be allowed, with 4 ambulances. To each infantry brigade, consisting of three battalions and staff, with a total of 3496 men, 2 field hospitals, and 4 ambulances will be allotted. A division will consist of 10,156 men of all ranks, with 12 divisional ambulances, 3½ field hospitals, and a grand total of 73 officers of the medical department. The grand total of an army corps will consist of 36,805 men of all ranks, with a medical staff numbering 297 officers, 2195 men, 568 drivers, and 1310 horses.

The above scheme certainly reads very well; but it at once becomes a question, so far at all events as the medical establishments are concerned, where are they to come from? The medical department is to furnish 297 officers, or, omitting the officers of the army hospital corps, 280 purely medical officers. As a liberal allowance, let it be presumed that 80 surgeons accompany the corps to which they are now attached, and it leaves a balance of 200 surgeons and surgeon-majors to be supplied from the staff of the United Kingdom. A reference to the last Army List will show that there are not more than that number at present serving on the staff at home who would be eligible to proceed on active service, and, be it remembered, this would drain all the large military hospitals of every effective man, and leave the sick of the army at home and the invalids from the seat of war to be provided for as best could be done.

In addition, it is to be borne in mind that the surgeons of the militia are gradually dying out, and, of course, if there was a war, and the militia were embodied, their medical attendance would have to be provided for as well. The present scheme of the Government is understood to be as follows:—The medical charge of the militia is to devolve on the medical officers of the regular service, more particularly on those who are in charge of depôt brigades; and in time of war the main portion of the work in the field hospitals will be performed by civilians hired for the occasion, at liberal salaries, from the ranks of the profession in the United Kingdom. Is it not self-evident that such a system must fail? Granting that Government is willing to pay civilians at the rate of £1000 a year for service in military hospitals, how many men worth their salt will be found willing to throw up their practices for the chance of employment for three, six, or twelve months, knowing full well that on their return they will find their posts occupied, and themselves with nothing to look forward to except to begin life all over again?

Be it remembered the Government has made provision for reserves in every portion of the army but the medical department, and that while it can count on men of means coming forward to officer the militia and volunteers, it is impossible to calculate on getting a supply of medical officers willing to sacrifice their own future for an ungrateful country.

This organisation looks very well on paper; but when put to a practical test it will prove an utter failure as far as the medical service is concerned. The strength of the army medical department is daily growing smaller; recruits cannot be obtained on the present terms, and at the current rate of decadence the medical service of the State will become hopelessly crippled within the next few years.
Yours obediently,
August, 1875. ARMY SURGEON.

Health of Ireland.

A quarterly report of the births, deaths, &c., just issued, states that, as compared with the preceding quarter, there has been a marked improvement in the sanitary condition of the country, the deaths registered being lessened by 5214. The deaths from small-pox numbered 225, showing a slight decrease as compared with the first quarter of the year. The deaths from this disease were distributed as follows throughout the four provinces:—Leinster, 8; Munster, 0; Ulster, 13; Connaught, 204. Abundant evidence is furnished by the observations of the registrars to show that the disease has been widely spread by the pernicious practice of inoculation. Every effort is being made by the authorities to detect the inoculators; but the difficulty of procuring such evidence as would make them amenable to justice is very great. Small-pox of a most malignant type broke out in Athenry district, Loughrea Union, and proved fatal in 40 instances. The deaths of 11 persons returned as centenarians were registered, including 2 stated to have been aged 105 years, one 108, and one 118. With reference to the last-mentioned, the registrar of the district, in reply to a special query respecting the case, furnishes the following information:—"I beg to state that my informant who signed the entry in the register, as being present at the death of the old man, was the son of the deceased. He told me he had, as well as others, frequently heard his father say that he was 41 years old when the French landed in Killala, in 1798, and the truth of this statement was never questioned. This would bring his age up to exactly 118 years. I may add that there were several persons present at the time of my registering the death, all of whom coincided in the opinion that his age was not, and could not be, less than that represented to me."

Spoonfuls.

To the Editor of The Lancet.

Sir,—It must have occurred in the practice of every medical man of any standing that over-doses of important remedies have been sometimes taken by their patients, from the old-fashioned habit of ordering mixtures in spoonful doses. To avoid this as much as possible, I have for years adopted the plan of using marked bottles in every case (where I could get them of the right size), and it is easy now to get of Messrs. Maw, Son, and Thompson, from Messrs. Wright, Sellers, and Layman, or from other sources, bottles marked in teaspoonful or tablespoonful doses as may be required. And I have had sets of labels printed; "one of the marked doses to be taken every —— hours," or "half one of the marked doses to be taken three times a day," specimens of which I enclose. With these the prescriber knows exactly how far he may go with important drugs, and unpleasant consequences such as I mention may be avoided. As coincident with the case in your article, I some months since had to treat a patient complaining of tickling cough, and I sent a linctus (which I had long been in the habit of using), containing a small quantity of belladonna, to be taken in dessertspoonful doses every two or three hours. This was forwarded in a three-ounce bottle without marks. My patient sent for me late at night in great haste. He had taken three doses of the medicine, he said, and was so horribly dry about the throat that he expected instant suffocation. He could not see distinctly, and felt quite dizzy and lightheaded. He had sat down to tea, and when he tried to swallow bread-and-butter it stuck in his throat, and he was choked, until by putting his finger in his mouth he had at last set up a little vomiting, and got some slight relief. He said he thought I must have poisoned him, and he begged to have some antidote administered. Himself and friends assembled at the house were in great alarm. I could only account for his state on the supposition that much more of his remedy had been taken than I intended; so I asked to have the mixture shown me, when I found, to my astonishment, that the bottle only contained half an ounce of fluid, and that his three doses (i.e., three dessertspoonfuls) had actually amounted to two and a half fluid ounces, instead of six drachms, as it should have been. The whole thing was explained, and I was able to reassure my patient. I got him to swallow some strong tea and some ammonia, and he soon recovered, although he was days before the pain in the throat and chest left him.

I have avoided similar unpleasantness since by giving strict orders to my dispenser to use only marked bottles for such things.

I remain, Sir, yours &c.,
Stansted Montfichet, Aug. 24th, 1875. Sydney Haynes.

E. K.—In order to ascertain whether the organic impurity is due to sewage contamination, it would be necessary to submit the water to a thorough chemical analysis. This could be done only by an expert. Before going to that expense, we advise our correspondent to see if the fault does not arise from a foul condition of the cistern. When was it last cleaned out? Is it well protected from the atmosphere? Is the waste or overflow pipe disconnected from the sewers? Many of the complaints that have reached us with respect to the bad water supplied by the metropolitan Water Companies have, on investigation, been traced to neglect of the above particulars.

We are compelled to postpone the publication of an article on Sir Robert Christison and Conjoint Schemes.

Treatment of Hernia by Inversion.

To the Editor of The Lancet.

Sir,—I was called to a man on the 21st inst., with an old oblique inguinal hernia on the left side. Not being able to reduce it as he bad hitherto done, I was sent for. He had been vomiting, and was in great pain. Failing to reduce it by the taxis, I put him in the position recommended by Dr. Thornton in The Lancet of the 14th inst., directing him not to meddle with it for four hours, at which time I called, and was pleased to find he had got it back after being three hours in that posture.

Yours faithfully,
Falmouth, Aug. 23rd, 1875. T. Stokes Guppy, M.D.

An Unprepossessing Tribe.

Mr. B. F. Hartshorne, in a communication to the section of Anthropology at the British Association, gave some interesting particulars of the social condition and habits of the Weddas of Ceylon. These curious people, it seems, still depend for their means of subsistence upon bows and arrows, and pass their lives in the vast forests of the country without any habitation, and without making the rudest attempt at cultivating the soil. No flint or stone implements are to be found amongst them, and they produce a flame by rubbing two sticks together. Their intellectual capacity is so small that they are unable to count or to discriminate colours. They are almost destitute of the religious sentiment, as well as of an appreciation of personal cleanliness, for they habitually eschew ablutions; yet, singularly enough, they abhor theft and lying. But perhaps the most remarkable trait in the character of the Weddas is the apparent absence of a faculty which is held to be peculiar to the human race—laughter. It is stated that they regard the expression of merriment by others with surprise and disgust, and not one of the Weddas was ever known to laugh.

Extensive Ulceration of the Os Uteri during Pregnancy treated by Nitric Acid.

To the Editor of The Lancet.

Sir,—During the month of April I was sent for to see a patient about five and a half months pregnant, who the midwife thought was miscarrying. On making inquiries I found she had been ill for some weeks past, and that for the last four days there had been so profuse a sanguineous discharge that she had become much weakened. She was also in a very depressed state of mind. On making a vaginal examination I found the lips of the womb gaping, much thickened, soft, but resisting. I was able to pass the index-finger about an inch and a half along the cervical canal, at which point it became very contracted and firm. The membranes could not be felt. The patient was then placed in a cool bed, with the hips slightly raised, and a sulphuric acid mixture ordered for her. When seen the next day she was still in a very low state, the bleeding not having abated in the least. I then introduced a Ferguson's speculum, and found the os extensively ulcerated, with blood exuding from the raw surface. Solid nitrate of silver was applied freely, and repeated in two days, which had the effect of completely stopping the bleeding. She was now treated with strong nitric acid, which was applied with the stiff side of a quill feather, the surface of the ulcer being quickly brushed over, and the feather passed for about half an inch up the cervical canal, there being cervical leucorrhœa present. The surface was cleaned with lint before each application of the acid. This was done at intervals of a week or a fortnight, according to the appearance of the ulcer, and at the same time a weak astringent lotion given her to use night and morning. Under this treatment she rapidly picked up strength, her spirits soon returned, and she is now quite well, and within a few weeks of her confinement.

It is well not to remove the speculum too soon after the application, as the fumes from the acid are liable to cause pain.

I remain, Sir, yours &c.,
Manchester, August, 1875. C. S. Richardson, L.K.Q.C.P., &c.

Subscriber.—1. We would advise our correspondent to procure the Registration Act. It can be obtained at the Acts Office (Spottiswoode's), New street-square, E.C.—2. Any duly qualified member of the profession is eligible for such appointments. Application should be made to the chief inspector for the district.—3. It can be obtained at the same time as the other Act.

Mr. Berridge.—We will make inquiries, and will give our correspondent an answer at an early date.

Romeo should consult a surgeon.

The paper of *Dr. Grainger Stewart* shall appear in an early number.

A Medical Sick Club.

To the Editor of The Lancet.

Sir,—Would you or any of your readers kindly inform me if there exists such an institution in connexion with the medical profession as a Club or Society conducted on the principles of the ordinary Friendly Societies scattered over the country. It would be a great boon to many, especially young men who have no accumulated store to fall back upon, to have some such staff of support should sickness or injury fall suddenly upon them. If there be no Society of the kind immediately connected with our profession, I should be obliged to any of your readers who would point out to me one of the ordinary Friendly Societies likely to answer my purpose.

Yours very truly,
Greenwich, Aug. 31st, 1875. Nemo.

⁂ Similar inquiries are frequently addressed to us. We should be glad to see a good Medical Sick Club established, and have no doubt it would prove a success.—Ed. L.

Refusal to Supply a Medical Officer of Health with Returns.

Dr. Horace Swete, medical officer of health for the Droitwich urban and rural districts, on issuing his first report, writes:—

> "Of prevalent diseases I can only speak from the small amount of personal observation I have had since May, and from the registrar's and union returns, the medical men in the town refusing to give me any information. This is from no want of courtesy to myself; but they say that, from a matter of principle, they ought not to give any assistance, or do any work, beyond their contract as district medical officers, without increased pay, and argue that, as the district sub-registrars are allowed payment for information of death to the medical officer of health, so ought they to be remunerated as district medical officers. I regret that there seems to be no means in the present law of giving these district officers any extra remuneration."

"A PRIVY ATMOSPHERE."

THE Cardiff Board of Health is likely to find its energies severely taxed, if the report of its medical officer does not overstate the condition of matters with which it has to deal. The district of Canton is, it seems, in a most deplorable state, what with defective cesspools, ditches flooded with fetid water, and pestilent pools, stinking and stagnant. The house refuse appears to be carried away by the floods occasionally, but by scarcely any other scavenger. The case is pithily summed up by the medical officer in a sentence: "The whole of the sanitary district of Canton had a regular privy atmosphere when I was last there." Remembering that the port of Cardiff is frequented by a considerable number of vessels in the course of the year, and that the sailors and other persons visiting Canton, to say nothing of the resident population, are liable to contract and carry away, as well as to increase, the diseases prevalent in this salubrious district, it will be interesting to know that the "main sewer" so long desired has been at length obtained, and that the immunity of the locality from serious disease is not wholly dependent on "lime."

M.D. Lond.—We understand that an Italian translation of Professor Balfour Stewart's work on Energy has just been issued, but we have not been informed of the name of the publisher.

DOCTORS AND DRUGGISTS.

WE have received a communication from *Mr. Garman* in reply to Mr. Rugg's letter in our last issue. We think the reply should come from Mr. O'Donovan.

ERRATUM.—In the tenth line of the second paragraph of Dr. Woods' paper on Thoracic Aneurism, published in our last number, page 308, for "anterior," read *external.*

COMMUNICATIONS, LETTERS, &c., have been received from — Dr. Aveling, London; Dr. Daly, London; Mr. Searle, Brixham; Dr. Browne, Belfast; Mr. Roberts, Derby; Mr. Lithgow, Wisbeach; Dr. S. Medical Diary for the ensuing Week.

Monday, Sept. 6.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10½ A.M. each day, and at the same hour.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1½ P.M. each day, and at the same hour.
ST. MARK'S HOSPITAL.—Operations, 9 A.M. and 2 P.M.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

Tuesday, Sept. 7.

GUY'S HOSPITAL.—Operations, 1½ P.M., and on Friday at the same hour.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 3 P.M.

Wednesday, Sept. 8.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. MARY'S HOSPITAL.—Operations, 1½ P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.
ST. THOMAS'S HOSPITAL.—Operations, 1½ P.M., and on Saturday at the same hour.
KING'S COLLEGE HOSPITAL.—Operations, 2 P.M., and on Saturday at 1½ P.M.
GREAT NORTHERN HOSPITAL.—Operations, 2 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M., and on Saturday at the same hour.
LONDON HOSPITAL.—Operations, 2 P.M.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2½ P.M.

Thursday, Sept. 9.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and on Friday at the same hour.

Friday, Sept. 10.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1½ P.M.
ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

Saturday, Sept. 11.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

NOTICE.

In consequence of THE LANCET being frequently detained by the Post Office when posted for places abroad *more than eight days after* publication, subscribers and others are reminded that such copies can be forwarded only as book packets, and *prepaid* as such.

TERMS OF SUBSCRIPTION TO THE LANCET.

POST FREE TO ANY PART OF THE UNITED KINGDOM.

One Year .... £1 12 6 | Six Months £0 16 3

TO THE COLONIES AND INDIA.

One Year £1 14 8

Post Office Orders in payment should be addressed to JOHN CROFT, THE LANCET Office, 423, Strand, London, and made payable to him at the Post Office, Charing-cross.

TERMS FOR ADVERTISING IN THE LANCET.

For 7 lines and under ....£0 4 6 | For half a page £2 12 0
For every additional line ... 0 0 6 | For a page 5 0 0

The average number of words in each line is eleven.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday; those from the country must be accompanied by a remittance.

N.B.—All letters relating to Subscriptions or Advertisements should be addressed to the Publisher.

Agent for the Advertising Department in France—

Mons. DE LOMINIE, 208, Rue Grenelle St. Germain, Paris.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 11, 1875.

ADDRESS TO STUDENTS.

ONCE more the rolling year brings us near to the commencement of another session at our medical schools, and once more in our "Students' Number" we collect the information relating to the various universities, colleges, hospitals, and schools of medicine which is of interest to those about to commence or to renew their medical studies. To all such we would offer, as is our custom, a word of welcome and advice.

The change of life from the rest or preparation of the months that are past to the busy work of those that are coming will probably be unwelcome to none—will be pleasant to most. The vast possibilities of the future are brought into more tangible reality by a sudden change to contrasted occupations, such as to many the 1st of October will imply; and the present is an earnest of the future. They have already some idea of what the words "study" and "examination" mean, and the consciousness of achievement which is produced by the successful passage of a preliminary ordeal gives a more vivid tint to the anticipation of future progress. Successive steps upwards seem less hard to climb when one is felt to be already firm beneath the feet.

We would suggest no discouraging reflection when we say that the task before you will need all the ardour, all the effort, you can bring to bear upon it. Its difficulties are not perhaps those most apparent to you. That "things are not what they seem" is true in many applications. The difficulties of life are rarely those which loom vast, with shadowy outline, in the early morning light. It is not the amount which is to be learned or obtained that is the real difficulty in the student's career. It is in the path by which you are to gain the end that the chief dangers lie. We purpose to devote our space to-day to some indication of the manner in which the path, with its slippery and uneven surface, its insidious pitfalls and enticing by-ways, may best be traversed.

To the work itself there is no need you should be urged. There are perhaps none who take the trouble to read the suggestions we have to offer, who are not earnest in their resolution to tread with unhesitating step and straightforward course the student's road. It is concerning the way to direct your good-intentioned will into effectual operation that you really need advice: what to do and what to avoid in your daily occupation; how so to economise your time and spend your effort as to obtain in the short period of your curriculum the best possible education for your future work.

The suggestions we have to offer you, the advice you need, relate to a twofold subject—how to work and how to rest. Work is to be the subject of your chief thought. That which is before you, could you have its details at once visible to you, would indeed appear colossal in its proportions. About twelve distinct regions of knowledge have to be traversed, comprehended in many separate courses of instruction. Each of these has to be mastered in more or less completeness, some in theory only, others by practical study as well. Happily the positions of difficulty have not to be at once encountered, and by successive conquest may all be won by ordinary ability and well-directed energy.

To speak first, therefore, of your work. The points on which you need suggestions refer less to what you should do than how you should do it. There are perhaps few students who, at the end of their hospital career, do not look back on time, effort, and labour wasted, because at first they did not know how to work. The whole system of instruction to which the student comes is to the large majority a strange one. The transition from book study to oral teaching is one to which the mental habits are not easily accommodated. The subjects of study are strange and unfamiliar. The method of inductive reasoning, on which the scientific elaborations presented to him are founded, is itself foreign, often, to his modes of conscious thought. Happily a certain proportion of students now come up well prepared, well grounded in preliminaries, not only classical, but physical and biological. It is perhaps impossible to exaggerate the advantage which is afforded by such a knowledge of the methods of reasoning employed in the natural sciences. We are glad to believe that a constantly increasing proportion of those who begin the more stern curriculum have been thus trained.

Let your work be uniformly steady. Prevent the need for "spurts." Do not attempt too much at first. Begin as you mean to go on, and go on as you begin. How long should you work a day? This will be in some measure decided for you. You should aim at reading three hours a day, apart from the lectures you attend and the practical work you are engaged in. If you do this and persevere in it, you will, if your work is rightly directed, be not far at the end of the session from the position at which you aimed. There are two styles of work. Some men will work unremittingly at one subject at a time, mastering it, and then passing to another. Others work uniformly at all the subjects they are studying, devoting daily such a time to each as shall enable them to make sure of the portion they have that day received. There can be no question that this latter method is that which yields the best results. It may not be so successful in obtaining prizes, but it will leave you with much more satisfactory knowledge and a much more honourable position at the end.

The ultimate end of your study is to obtain a well-grounded knowledge of the three great divisions of medical science and art—medicine, surgery, and midwifery. They constitute the triple structure which you are to build, and it is to be erected on a triple foundation. Anatomy, physiology, and chemistry are the three corner stones on which the erection is to be based. Ancillary, and important in subordinate positions, are the collateral sciences of botany, comparative anatomy, and zoology. Materia medica, medical jurisprudence, and hygiene are, in effect, based on and compounded of other sciences.

All these studies differ from those which will probably have occupied your preceding attention in the circumstance that their facts are isolated in their presentation, in varying degree it is true, but more or less in all. In many other branches of study the facts are so linked together that they are repeatedly brought before the student's attention. The demonstrations of mathematics are involved in the discussion of subsequent problems, in substance and in method, to an extent which renders their retention in the memory easy. The facts of classical studies, the meaning of words, the construction of sentences are constantly recurring in fresh association but repeated similarity, so that they are indelibly imprinted on the memory and can be retained with little conscious effort on the part of the learner beyond that involved in their acquirement. With the physical, and especially with the medical, sciences it is very different. Few facts in anatomy involve any which have gone before. The result is that the student, in acquiring new facts, is constantly liable to forget the old, however well he may have learned them. Hence it is necessary to ensure, by constant, diligent, forced repetition, the retention of that which has been already acquired. There is no subject of study in which this is not necessary; but the need for it is much greater in some than in others. The disjunction of fact in some medical sciences is painfully complete, extending down to the minutest details. In others it is less so. But with respect to all it is true that, for any effectual retention of the facts acquired, frequent repetition is necessary. The student should aim at keeping fresh in his memory that which he has before learned, so that at any moment his past acquirements may be as accessible and as accurate as those of the most recent date. This is difficult, needs much perseverance, but is indispensable for successful study. It is the only system which will rob coming examinations of their terror and enable you to dispense with the help of the "grinder."

A large proportion of the knowledge you acquire has to be conveyed to you by the use of symbols. A proportion, also large and happily every day increasing, is learnt by actual observation, by obtaining evidence with the various senses of the facts in question. Different minds will appreciate in different degrees the respective methods. To all the method of actual observation is of incalculable value, impressing the facts upon the mind, and training the student to look beyond occurrence for cause, to search for the operation of the law of sequence, which is the great problem of medical practice, and which is indispensable to any efficient exercise of medical skill. In recording facts, observations, and statements made to you, vary the symbolic method you employ. Wherever you can, let a diagrammatic representation aid the written note. The roughest sketch or diagram, wholly inartistic, will prove of the greatest value in fixing on the mind a relation which no description could accurately convey.

This leads to the question how far you should take notes of the lectures you have to attend. On this no general rule can be given. Most men find that they can attend better, can carry away even in memory more of what is said to them, when they take notes than when they do not. With others it is not so; the attention, unembarrassed by any mechanical occupation, can receive, and the mind retain, far more when the hands and mind are at rest. It will vary, too, with different lecturers. The care in the collection, in the classification, in the presentation of facts which some lecturers take, renders their lectures of so much value that it is well to secure as much of them as possible. When you do take notes, endeavour to take at the time such notes as you can keep permanently. The time spent in writing out notes is often time absolutely wasted. Moreover, it is a dangerous waste of time. The student is apt to fancy, when he has written out his notes, that he has learned them. The facts have become familiar; he can, perhaps, recall the chief in detail; but as a rule, under the circumstances, they are not learned. The facts speedily vanish from the mind. Therefore, if you do write out notes a second time, take care that you learn them thoroughly as well; and do not mistake the act of writing out for the operation of learning them, similar as they may at the moment seem.

Some of the subjects of your study are to be learned in practice as well as in theory. This is the case, to the greatest extent, with anatomy. There are very few facts of anatomy which you have to learn which you cannot verify for yourselves. With physiology and chemistry it is so to a less degree. In medicine and surgery the facts are capable of verification to a great extent, but not with such completeness as in anatomy. It is one of the greatest improvements in the medical schools of the present day that practical instruction is carried to almost the highest point to which it can be brought. Many subjects which before were taught in theory only are now taught, and very thoroughly taught, in practice also. It is so in histology, normal and morbid; it is so in chemistry; and it is so in many parts of physiology. Make, therefore, the utmost possible use of your opportunities of acquiring the practical knowledge, which is so much more easily retained and so much more usefully reproduced when needed, than any mere theoretical knowledge; but be careful not to content yourself with practical work. You must study and think as well as observe. There is great danger in allowing the mechanical to take the place of the intellectual. It is so especially in anatomy. The student dissects carefully, and imagines that by careful dissection, by careful "cleaning" of his parts, he is learning their anatomy. He may be, but is not necessarily doing so. He must supplement his practical work with careful reading and thoughtful observation. He may economise much precious time by accurately observing the position and relation of that which he has dissected. But in any case dissections must be thoroughly learned. Note carefully the connexions between the different objects in the region you are dissecting. Endeavour, as far as you can, by careful systematising, to reduce everything to well arranged and ordered form. The increased power and knowledge will be much more than recompense for the additional trouble which the method gives you.

The arrangements of the curriculum will probably seem to you in many respects unreasonable. They are not perfect; but bear in mind that the parts which seem to you to be faulty have objects which you may not now perceive. Patiently endeavour, then, to make the most of what appear to you its useless provisions. Your patience will often be tried by having to listen to what seem out of place accounts of departments of knowledge as yet quite unfamiliar. Do not "cut" lectures because you do not see their value. Endeavour to attend them regularly, and to carry away as much as you can, and you will find your subsequent work in other subjects, as well as in that department, rendered easier.

With reference to the later studies of medicine and surgery we would repeat what we said of the earlier ones—embrace every opportunity of acquiring knowledge practically by direct observation. Examine patients for yourselves—touch, feel, handle, listen wherever you can. You cannot educate too carefully your senses to appreciate the signs of disease. In the majority of cases those signs may be indubitable and obvious; but in others, frequent enough, they are so obscure as to need all your knowledge, all your tact, all your practice to recognise and weigh them. These remarks, generally applicable as they are, apply with much force to the post-mortem appearances of disease. Lose no opportunity of witnessing post-mortem examinations. If you have seen the cases during life so much the better; but whether you have or not, attend the examination after death. Make yourselves thoroughly familiar with the normal appearance of organs and with the variations from the normal which may be met with apart from actual disease. It is impossible to exaggerate the importance of your present careful study in the deadhouse. You will have opportunities throughout life of keeping up and improving your clinical knowledge. Every day's work is a day of clinical practice. But when you are engaged in actual practice, opportunities for pathological observation will come rarely; but when they do come, on your knowledge and experience important issues will often depend. If the knowledge which might have been acquired during student-life is not gained, the opportunities of obtaining it will probably not recur, and the loss will be life-long.

In the wards, do not let your desire to observe for yourselves carry you, as it does with a large number, chiefly where observation is easiest. The eye is the organ most easily educated; do not give it, therefore, an exclusive share of attention. Exercise your other senses. Do not be always running after sensational cases, or hanging over the rails of the operating theatre. If you are working at surgery or medicine, examine the patients when the dressers or clerks are working, and then, having learned the signs and symptoms of the cases, attend the surgeons' and physicians' visit, to hear their remarks and note what you have failed to observe.

It follows from what we have said that you should make it one of your first objects to hold practical posts in the hospital. Despise nothing, however low, that gives you scope for the exercise and improvement of your knowledge. When you have the actual treatment of patients entrusted to you, note carefully the results of the remedies you employ. Do not prescribe and take no notice of the effect of your treatment, but look diligently for, and note the absence as well as the presence of the results you expected to follow. Above all, you should study and think over the cases you see. Read up every important case you meet with, and endeavour to fix its salient points in the memory, so as to become familiar with those that are typical of the disease.

To turn now from your work to the other object to which your time must be devoted—rest. How to rest is in importance second only to how to work. The opposition of terms is not, perhaps, that which seems most natural to the junior student. To those who are ending their work it may have a more obvious significance. "Work and play" is the usual time-worn antithesis. "Play," however, is a term which accords better with the amusements of the schoolboy than of the student. It implies an elevatiou of a pastime, a relaxation, into an object of primary importance. If you wish to be successful, to acquire fairly the knowledge needful and for which you are sent to a medical school—if you wish to fit yourselves for future work in life, you must first of all learn to subordinate, in thought and action, your recreation to your work. The recreation you take should be of such a kind as will best fulfil its end—to re-create and strengthen your powers. It is on this account, and no other, that you should choose it. What it, then, should be you must allow your strength and opportunities to decide. It should be one which provides effectual change of thought and occupation. It should give a sufficient amount of exercise, and exercise in the open air is essential for its due beneficial effect. It should leave no unpleasant after-taste, physical or moral. It should not be one which has for you any special seductive attraction, which may now or at some future time prove too powerful to be effectually repressed. You may be fonder of one amusement than of another; you may have more natural aptitude for one than for another. Beware how you allow your inclination or your aptitude to be your guide in electing your habitual recreation. In so far as you allow these, rather than its effect, to guide you, you raise recreation from its subordinate position and make it an end instead of a means.

Bear in mind at all times the responsibilities of your profession. You will hear much of them in the opening addresses, and we will not dwell upon them now. We will only urge you, above all, to cultivate tenderness to the sick under your charge, not only in action, but in word and even in thought. You will often have to inflict physical pain, sometimes to cause mental suffering; but let the latter as well as the former be as little as possible. How much pain is caused to sick persons by thoughtless, inconsiderate modes of expression is incalculable. Remember that you come in contact with the tenderest points of their nature. The expression or the gesture or the slight neglect which has in it nothing in itself blameworthy, which would cause no annoyance to a healthy person, may to them be a source of much distress, of pain as real as any you inflict upon them physically. Pain, disease, and death are hardly more than names to your subjective life; to those to whom they are the realities of the present or the nearer future they change the whole course of thought and feeling. Beware, then, how you judge the sick by the standard of the healthy. Endeavour to enter into their feelings. Bear with the irritability which may be annoying to you, the obstinacy which may vex you and render your own task needlessly difficult. Invest suffering in another with that reverence which is due to its sad mystery. It has its roots deep down beneath the surface of our life, and reaches, in each, the inner depths of calm or storm, in a region into which you cannot pass, except by tender sympathy and thoughtful care.

THE COURSE OF STUDY REQUIRED OF A MEDICAL STUDENT.

THE object held in view in the compilation of the present "Students' Number" has been to provide for those about to enter the medical profession reliable information as to the course of study required, the examinations they will have to pass, the regulations to which they will have to conform, &c. To this end we have given in the preceding and following pages the regulations of the examining bodies and the prospectuses of the several medical schools, and we propose in this article to describe the whole course of study, stating what lectures have to be attended, what appointments held, &c.

The medical student's year is divided into two sessions: one of six months, the winter session; the other of three months, the summer session. The winter session extends from October 1st to March 31st, and the summer session from May 1st to July 31st. New students usually enter a hospital or medical college on the 1st October, and this date is looked upon as rather an important one. It is the custom at most schools for an introductory address to be given to the students by some member of the staff on that day, and this often attracts a large number of old students to the hospital. These introductory addresses frequently contain much excellent advice—the offspring of their authors' experience.

Supposing, then, a new student enters on the 1st October, he will find the work of his first winter session somewhat as follows:—He will be required to attend lectures on Anatomy, Physiology, and Chemistry—all, especially the first two subjects, of extreme importance. Anatomy and Physiology are sciences an accurate knowledge of which is essential to every medical man. We therefore earnestly recommend the student to pay great attention to the study of anatomy and physiology. The first part of anatomy which he will have to learn will be the "bones," and these he should thoroughly master, as an accurate acquaintance with them will simplify greatly the acquisition of a knowledge of the other structures of the body. The student should also take the first opportunity of dissecting, and he should be careful, while dissecting, not to be content merely with using his forceps and scalpel, but to read up diligently the anatomy of the part on which he is engaged, and make himself thoroughly familiar with the relations of the different organs and structures. Physiology should be taken hand-in-hand with anatomy, of which it is the complement, teaching us the peculiarities, structure, and functions of those organs of which anatomy teaches us the form and situation. It is a science of the very greatest importance as a foundation of medical knowledge, and without an acquaintance with it no man can become a competent medical practitioner. Of the importance of Chemistry we must also speak highly, though we think it would be an excellent custom for students to obtain a knowledge of chemistry before commencing their regular medical course. At any rate it is a science a knowledge of which is essential, and which therefore must be studied assiduously. In addition to attending these three courses of lectures, there will be the out-patient departments of the hospital to be visited, where the student will find excellent opportunities of gaining a practical acquaintance with the simpler and more common forms of disease. He must be careful, however, not to allow himself to be beguiled into spending too much time in these seductive departments, but must consider that the dissecting-room should be the home of the first-year's man.

The next session is the first summer, and the lectures of this period are on Botany, Materia Medica, and Practical Chemistry. These are important subjects in their way, Materia Medica particularly so, as it is of the greatest importance that the medical man should be thoroughly acquainted with the action and effects of the remedies placed in his hands. It should be remembered that during the past few generations the various departments of purely medical knowledge have made enormous strides, and immensely extended their boundaries, so that the student of to-day is compelled to learn a vast deal more than was the student of fifty years ago. On this account every subject not absolutely necessary should be omitted from the medical course. Practical Chemistry is of importance, as it teaches us the art of analysis, and thus becomes essential in the conduct of various medico-legal inquiries, in the investigation of questions of purity of water-supply, and in other sanitary considerations.

The first summer session over, the student should, if possible, get a good holiday and change of air, in order that he may come back invigorated and strengthened for his second winter, as this session will involve very hard work, and will test his strength and energies to a considerable extent. He will again attend lectures on Anatomy and Physiology (if he is working for the London degree, on Chemistry), and on Medicine and Surgery. He will also have to dissect and to dissect diligently, and to read hard at the same time, as at the end of this session will be the time for him to present himself for his primary examination, known among London students as the "first College." It is, we think, important to the student that he should, if possible, take up his examinations at their proper time. By doing so he is enabled to follow a regular scheme of work, and to study each subject in its proper time and place without confusion or crowding up together, and this renders the work easier and less irksome to him. Especially would we recommend him to pass his primary examination after his second winter. The passing of this examination forms a kind of landmark, as it were, in his course, and is, in fact, the division between what may be looked upon in some sense as the preparatory or foundational portion of his studies, and the more decidedly practical portion. The "first College" passed, the student is more free to pursue the study of medicine and surgery, both systematic and clinical. During his second winter, in addition to attending the lectures we have named and studying his anatomy, he will be expected to appear in the wards and out-patient department of his hospital, and to attend the clinical lectures. We should not advise him to take any appointment as dresser or clinical clerk until the "primary" has been passed. Altogether, the second winter is a session of almost incessant work, and is, in fact, the hardest part of the course.

The second summer session also brings with it plenty of occupation, especially for the candidate for the London University degree, as at the end of it will be the time for his first M.B. examination. The lectures of the second summer are those on Midwifery, Medical Jurisprudence, and Pathology; in some schools this last subject is taken later. This session is the time for the student to take some hospital appointment as out-patient, dresser, or clinical clerk, since, not having many courses of lectures to attend, he will be able to spend plenty of time at his duties, and in the wards and post-mortem room. We would strongly impress on the student the immense advantages which may be gained by hospital appointments if the opportunities they afford are rightly used, and if he is not content with merely going through his duties *as duties*, but takes a real interest in the cases, and endeavours always to gather knowledge and experience from them. The greater the number of appointments a man can hold the more thorough and varied will be his knowledge of his profession, and he should endeavour to gain acquaintance with all the special branches by holding dresserships and clerkships in the ophthalmic, aural, dental, and cutaneous departments.

The second summer session over, the student now settles down to the practical study of medicine and surgery. He has studied the auxiliary and collateral branches and now comes to the actual practical application of the principles which he has learned. He should therefore be diligent in his attendance at the hospital practice and clinical lectures, and also at the descriptive and systematic courses on medicine and surgery.

At the end of the third winter some students present themselves for their pass examinations; this, however, can only be done by those who have spent a year in study, after passing the preliminary and registering, before entering at a hospital.

If the commencement of professional education and the commencement of hospital work were synchronous, the four years must be completed before the student is eligible for his diploma. This fourth year some students spend in performing the duties of assistant to some medical practitioner, while others prefer to continue in attendance at the hospital. We think the latter is the better course; the hospital presents facilities for learning which can never be found in private practice, and therefore the student should get as much of it as he possibly can.

At the end of the fourth year the student will be eligible for his final examinations; and here we will leave him, and trust that the few remarks we have made may serve as a guide to those about to enter our profession, and, by showing what is expected from them, enable them to make the most of the opportunities afforded them, and spend their time to the best advantage. And now we will conclude by wishing all our readers a brilliant career as students, and a bright and prosperous future as practitioners of the medical art.

CHANGES AT THE METROPOLITAN MEDICAL SCHOOLS.

The changes in the tutorial departments of the metropolitan medical schools and hospitals have not been very numerous or important during the past year. Beyond the usual wear and tear of time, matters have remained in a condition somewhat similar to that in which they were last year. With the lamentable exception of the premature decease of Dr. Anstie, the hand of death has had no part in the recent changes, which have been mostly wrought by the migration of teachers from one school to another, or by retirement and the filling up of vacancies.

Although no new professorship or lectureship of any importance has been established during the past twelve months, there has evidently been an urgent desire on the part of the authorities of all the medical schools to increase the attractions, and, what is more, to enhance the tutorial value of the institutions with which they are connected.

At *Charing-cross* Dr. J. Pearson Irvine has succeeded Dr. Dowson as lecturer on Botany, and has also been appointed lecturer on Diseases of Children in place of Dr. Mitchell Bruce, who is now associated with Dr. Silver as lecturer on Theoretical and Practical Physiology. This hospital and medical school has sustained a serious loss in the resignation of Dr. Vivian Poore, who, as will be seen below, has returned to his *alma mater*, University College. In consequence of Dr. Poore's resignation, the lectureship on Forensic Medicine, and one of the joint lectureships on Public Health are vacant, as well as one of the assistant-physicianships to the hospital. Mr. J. F. Blake has succeeded Mr. Garrod in the chair of Comparative Anatomy. Mr. Bolas is demonstrator of Chemistry. In the hospital, with the exception of the vacancy caused by Dr. Poore's resignation, the only change is that Mr. A. Duncan, M.B., has been appointed medical registrar.

At *Guy's*, owing to the retirement of Mr. John Birkett, Mr. Cooper Forster takes the rank of senior surgeon, and Mr. Howse has been promoted to a full surgeoncy, while Messrs. Lucas and Golding Bird have been appointed assistant-surgeons. Mr. Thomas Bryant and Mr. Durham have succeeded Mr. Birkett and Mr. Cooper Forster as lecturers on Surgery. Mr. Howse and Mr. Davies-Colley are now the lecturers on Anatomy. Mr. Jacobson has succeeded Dr. Pye-Smith in the chair of Comparative Anatomy.

At *King's College* the vacant Professorship of Physiology, caused by Dr. Rutherford's migration to the Edinburgh University, has been filled by the appointment of Dr. Gerald F. Yeo, and Mr. S. Hamilton Cartwright has been appointed professor of Dental Surgery. In the hospital Dr. J. Curnow and Dr. E. B. Baxter have been appointed assistant-physicians. Mr. Hamilton Cartwright has been made dental surgeon, and Messrs. Batterbury and A. B. Barrow have been appointed Sambrooke registrars.

At the *London Hospital*, by the retirement of Dr. Head, Dr. Palfrey has become sole obstetric physician, also lecturer on Midwifery and Diseases of Women. Dr. Herbert Davies and Dr. S. Fenwick have succeeded Dr. Ramskill and Dr. Langdon Down as lecturers on Medicine. Mr. E. B. Aveling has been appointed to the chair of Comparative Anatomy.

At *Middlesex* Mr. Hulke has been appointed joint lecturer on Surgery with Mr. De Morgan. Dr. Arthur Edis will give practical demonstrations on Diseases of Women and Children, and Mr. Karop has been appointed one of the demonstrators of Anatomy. The Chemistry chair is vacant. At the hospital Dr. Coupland has been made curator of the museum and pathologist, and Dr. Henry Humphreys and Dr. R. W. Lyell are the registrars.

At *St. Bartholomew's*, by the retirement of Dr. Harris, Dr. Church has become full physician, Dr. Brunton having been appointed to the post of assistant-physician. Dr. Godson has been made the new assistant obstetric physician, and Dr. Hall and Dr. Moore casualty physicians. Mr. Mills is the special administrator of chloroform. Dr. Moore has succeeded Dr. Church as lecturer on Comparative Anatomy. Several complimentary exchanges appear to have been made by the demonstrators of special subjects. Mr. Willett, for instance, is announced in one part of the prospectus to have given up Orthopædic Surgery to Mr. Langton, in order that he might relieve Dr. Duckworth of the demonstrations on Diseases of the Skin. On the other hand, it is stated that in order that Mr. Langton may conduct the demonstrations on Orthopædic Surgery, he has transferred patients with diseases of the ear to Mr. Morrant Baker, who, curiously enough, is also advertised to take charge of patients suffering from diseases of the skin. Mr. Willett's case is especially trying, for in addition to his duties as demonstrator of Diseases of the Skin, and surgeon in charge of orthopædic patients, he has to give demonstrations in Practical Surgery.

At *St. George's* Drs. Ogle and Dickinson are the lecturers on Clinical Medicine, *vice* Drs. Wadham and Dickinson. Messrs. Pollock and Rouse are the lecturers on Clinical Surgery, in place of Messrs. Prescott Hewett and Henry Lee. Mr. Pick is the lecturer on Anatomy, *vice* Mr. Rouse; Dr. Ralfe the lecturer on Physiological Chemistry, in place of Mr. M. S. Moore; while Dr. R. J. Lee has succeeded Mr. J. W. Haward as lecturer on Morbid Anatomy. Dr. Barnes has been appointed successor to Dr. John Clarke in the chair of Midwifery and Diseases of Children. Mr. Haward conducts the class of Practical Surgery, and Dr. Brailey has succeeded Dr. Cavafy as lecturer on Comparative Anatomy. At the hospital Dr. Barnes has been made obstetric physician. Mr. Prescott Hewett, who recently retired from the working staff, has been made consulting surgeon, and Mr. Rouse has been promoted to a full surgeoncy, while Mr. Pollock takes rank as senior surgeon. Mr. Haward has been elected to the assistant-surgeoncy thus rendered vacant.

At *St. Mary's* very few changes have taken place. Mr. A. B. Prowse has been appointed assistant-demonstrator of Anatomy, and Dr. Mahomed demonstrator of Morbid Anatomy, and medical tutor and pathologist.

At *St. Thomas's* Dr. Gervis has succeeded Dr. Barnes as lecturer on Midwifery. Dr. Stone is the sole lecturer in Forensic Medicine, and Dr. Greenfield is associated with Mr. Henry Arnott in the lectureship on Morbid Anatomy and Practical Pathology. At the hospital Dr. Stone has been appointed to the post of physician, rendered vacant by Dr. Clapton's retirement; Dr. Gervis has become obstetric physician, and Dr. Cory assistant obstetric physician. Mr. W. Verdon has succeeded Dr. Greenfield as medical registrar; while Mr. MacKellar is now associated with Mr. Croft as demonstrator of Practical and Manipulative Surgery.

In *University College* Dr. Ray Lankester has been elected professor of Comparative Anatomy and Zoology, and Mr. Maclean and Mr. A. P. Gould have been appointed demonstrators of Anatomy. At the hospital the changes have been more numerous and more important. By the resignation of Sir Henry Thompson, and the partial retirement of Mr. Erichsen, two vacancies were caused in the surgical staff, to fill which Mr. Christopher Heath and Mr. Berkeley Hill were appointed to the charge of in-patients, and Mr. A. E. Barker, of Dublin, was elected assistant-surgeon. In consequence of the new arrangement, under which Sir W. Jenner and Dr. Reynolds visit the hospital by turns in the winter and summer sessions, Dr. Ringer has been appointed to the charge of in-patients, and Dr. Vivian Poore has been elected assistant-physician, while Dr. Gowers has been appointed assistant teacher of Clinical Medicine.

The changes at the *Westminster* School cannot be better described than in the words of the report of the Dean, Mr. Cowell:—"Shortly before the beginning of the winter session the school had to lament the loss of Francis Edmund Anstie, one of the distinguished physicians of the hospital, and its able Lecturer on Medicine. He was cut off suddenly, in the prime of life, a victim to the profession he loved so enthusiastically and well, and in which he had gained a high reputation. It is not easy to give expression in words to the high sense which both colleagues and pupils entertained of the ability, energy, and kindliness which he ever evinced in his intercourse with them, and in promoting the interests of the school. Neither will it be easy to forget that September morning and the throng of sad faces in the country churchyard of Friern-Barnet, where Dr. Anstie rests. The gap thus made in the hospital staff was filled by the promotion of Dr. Gibb, and Dr. Donkin was appointed to the post of assistant-physician. A few changes in the school have also been necessary. In the emergency last winter session, Dr. Basham and Dr. Fincham kindly undertook to deliver the lectures on Medicine. The chair has now been filled up by the appointment of Dr. Fincham and Dr. Sturges as joint-lecturers on Medicine. Dr. Phillips has succeeded to the chair of Materia Medica, and Mr. Malcolm Smith, M.B. and Master of Surgery of the University of Edinburgh, has been appointed the sole demonstrator of Anatomy. He will attend daily in the dissecting-room, and, under the lecturer, thoroughly superintend the practical study of anatomy. Further steps have been taken to complete the Dental department by the appointment of Dr. Allchin to teach Dental Anatomy, Physiology, and Histology, during the summer session, and of Dr. Dupré, F.R.S., to teach Mineralogy during the latter half of the winter session. Mr. Walker will continue to lecture on Dental Surgery and Pathology during the former half of the winter session, and a second dental surgeon will be appointed to attend at the hospital once or twice a week, and to teach Dental Mechanics during the summer session." Dr. F. De Havilland Hall has been appointed medical registrar.

SESSION 1875-76.

GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

Registration of Medical Students.—The following regulations have been adopted by the General Medical Council in reference to the registration of students of medicine:—1. Every medical student shall be registered in the manner prescribed by the General Medical Council. 2. No medical student shall be registered until he has passed a preliminary examination, as required by the Medical Council. 3. The commencement of the course of professional study recognised by any of the qualifying bodies shall not be reckoned as dating earlier than fifteen days before the date of registration. 4. The registration of medical students shall be placed under the charge of the branch registrars. 5. Each of the branch registrars shall keep a register of medical students according to the prescribed form. 6. Every person desirous of being registered as a medical student shall apply to the branch registrar of the division of the United Kingdom in which he is residing, and shall produce or forward to the branch registrar a certificate of his having passed a preliminary examination as required by the Medical Council, and a statement of his place of medical study. 7. The branch registrar shall enter the applicant's name and other particulars in the Students' Register, and shall give him a certificate of such registration. 8. Each of the branch registrars shall supply to the several qualifying bodies, medical schools, and hospitals, in that part of the United Kingdom of which he is registrar, a sufficient number of blank forms of application for the registration of medical students. 9. The several Branch Councils shall have power to admit special exceptions to the foregoing regulations as to registration, for reasons which shall appear to them satisfactory. 10. A copy of the Register of Medical Students, prepared by each of the branch registrars, shall be transmitted, on or before December 31st in each year, to the registrar of the General Council, who shall, as soon as possible thereafter, prepare and print, under the direction of the Executive Committee, an alphabetical list of all students registered in the preceding year, and supply copies of such authorised list to each of the bodies enumerated in Schedule A to the Medical Acts, and through the branch registrars to the several medical schools and hospitals. 11. The several qualifying bodies are recommended not to admit, after October, 1870, to the final examination for a qualification under the Medical Acts, any candidate (not exempted from registration) whose name has not been entered in the Medical Students' Register at least four years previously.

REGULATIONS
OF THE
MEDICAL EXAMINING BOARDS IN THE UNITED KINGDOM.

UNIVERSITY OF OXFORD.

Every student must reside in one or other of the Colleges or Halls, or in licensed lodgings, for a period of three years, passing at least two examinations in Arts, and one in either Mathematics, Natural Science, Law, Modern History, or Theology, when, if he obtain a first, second, or third class, he can take his B.A. degree; if he do not gain such honour he has to pass a third examination in *Literis Humanioribus*.

A student deciding to graduate in Medicine must pass the requisite examinations for the degree of B.A., and afterwards spend two years in study* prior to the first or scientific examination for the degree of Bachelor of Medicine, and two years more prior to the final or practical examination for the same degree. Evidence must be brought to show that he has studied the practical parts of his profession in a first-class hospital.

A dissertation has to be publicly read, three years after the M.B., for the M.D.

The instruction in Natural Science is carried on at the Museum, where there is practical instruction in Physics, Chemistry, Anatomy, and several other departments of natural science, together with courses of lectures and of practical instruction and work, by the several professors. Large collections illustrate the various subjects. There is a pathological series, including the collection of Schroeder Van der Kolk, in the medical department, and a medical and public health laboratory. The Radcliffe Library, containing above 20,000 scientific volumes, is open to all students daily from ten to four, and on certain evenings during term. There are also lectures and practical instruction in Botany at the Botanical Gardens, and clinical instruction at the Infirmary.

The medical examinations take place annually in the Michaelmas term.

Scholarships of about the value of £75 are obtainable at Christ Church, Magdalen, and other colleges, by competitive examination in Natural Science. Every year a Radcliffe Travelling Fellowship is competed for by any who, having taken a first class in any of the schools, or having obtained a University prize or scholarship, propose to study Medicine. The Travelling Fellows receive £200 a year for three years, half this period being spent in study abroad.

More detailed information may be obtained from the University Calendar; from the Regius Professor of Medicine; from the professors in the several departments; from E. Chapman, Esq., M.A., Frewin Hall; and from the Sub-Librarian in the Radcliffe Library, or the Museum.†

UNIVERSITY OF CAMBRIDGE.

The student must enter at one of the Colleges, or as a non-collegiate student, and keep terms for three years by residence in the University. He must pass the previous examination in Classics and Mathematics, which may be done in the first or second term of residence, or, through the Oxford and Cambridge Schools Examination Board, before commencing residence. He may then devote himself to medical study in the University, attending the hospital and the medical lectures, dissecting, &c. Or he may proceed to take a degree in Arts, either continuing mathematical and classical study, and passing the ordinary examinations for B.A., or going out in one of the Honour Triposes. The Natural Science Tripos is preferred by most medical students, some of the subjects for this Tripos examination (Chemistry, Botany, and Comparative Anatomy) forming part of the series of medical study.

The expenses of residence, lectures, &c., at a college are about £150 per annum; but these are in many cases lessened by scholarships, ranging in value from £20 to £80 a year, which are very numerous, and obtainable by most students of industry and ability. They are chiefly given for mathematical and classical proficiency. Some may be obtained at once, even before entering; and notices of the times of examination for these are given from time to time, under the head of "University Intelligence," in *The Times* and other newspapers. Scholarships are given for Natural Science in Trinity, St. John's, St. Peter's, Clare, Christ's, Sidney, Pembroke, Caius, and Downing Colleges; the examinations being at Easter, and in June and October.*

Non-collegiate students can reside at less expense than those who enter a College. They are allowed to attend certain of the College lectures and all the professors' lectures, and have the same University status and privileges as the other students. They are under the superintendence of the Rev. R. B. Somerset, Orford House, Cambridge, from whom further information may be obtained.

For the degree of *Bachelor in Medicine* five years of medical study are required, except in the case of medical students who have graduated with honours as Bachelors of Arts, four years being then sufficient. This time may be spent in Cambridge or elsewhere. The earlier part of it is usually spent in Cambridge, the student remaining in the University till he has passed the examination for the Natural Sciences Tripos and the first and second examinations for M.B.

There are three examinations for M.B. The *first* in Mechanics and Hydrostatics, Chemistry (with heat and electricity), and Botany. The *second* in Anatomy and Physiology (Human and Comparative) and Pharmacology. The *third* (at the conclusion of medical study) in Pathology and the Practice of Physic, Clinical Medicine, and Medical Jurisprudence. The examinations are partly in writing and partly oral, in the hospital, in the dissecting-room, and in the laboratories. They take place twice annually (in June and December).

An Act has to be kept, which consists in reading an original thesis and passing a *vivâ voce* examination on the subject of the thesis and on other subjects.

Previously to the first examination, lectures must have been attended on Chemistry (with manipulations) and Botany. Previously to the second examination the student must have attended lectures on Anatomy and Physiology (Human and Comparative), Materia Medica and Pharmacy, and Pathology; have Dissected one season; and attended Hospital Practice one year. Previously to the third examination lectures must have been attended on the Principles and Practice of Physic, Clinical Medicine, Clinical Surgery, Midwifery, and Medical Jurisprudence; also Hospital Practice for three years. The candidate must also have been a clinical clerk, or have had special charge of patients in a hospital, dispensary, or parochial union, for six months.

The degree of *Doctor in Medicine* may be taken three years after M.B. An Act has to be kept, with *vivâ voce* examination; and an extempore essay has to be written on some subject relating to physiology, pathology, the practice of medicine, or State medicine. A Master of Arts proceeding to M.D. is required to produce the same certificates and pass the same examinations as for M.B.

For the degree of *Master in Surgery* the candidate must have passed the three examinations for M.B., and have attended lectures on Human Anatomy (a second course), on the Principles and Practice of Surgery, Clinical Surgery, Midwifery (with ten cases); he must have dissected a second season, have attended the Surgical Practice at a recognised hospital for three years, and have held a house-surgeoncy or dressership for six months. He is then required to pass an examination in Surgical Anatomy, Pathology and the Principles and Practice of Surgery, and Clinical Surgery.

An examination in so much of State Medicine as is comprised in the functions of Officers of Health will be held in Cambridge in October, 1875, beginning on Oct. 5. Any person whose name is on the Medical Register of the United Kingdom may present himself for this examination provided he is twenty-four years of age. The examination will be in two parts. All applications for admission to this examination or for information respecting it, should be addressed to Professor Liveing, Cambridge.

The following is a summary of the course which a student (commencing at the University, say, in October, 1875) may follow:—He enters at any one of the colleges, or as a non-collegiate student, and passes the previous examination (in Classics and Mathematics) in October, 1875, or in April, 1876, unless he has already passed the equivalent examination under the Oxford and Cambridge Schools Examination Board. He is then registered as a student of medicine. Medical study in the University for two years. Natural Sciences Tripos examination (in Comparative Anatomy, Chemistry, and Botany), June and December, 1878; this admits to B.A. degree in June, 1878. Second examination for M.B. (in Human Anatomy and Physiology, and Materia Medica), May, 1879. Third examination for M.B. (in Pathology and Practice of Physic, Clinical Medicine, and Medical Jurisprudence), November, 1880. Examination for M.C. (in Surgical Anatomy, Pathology, and the Principles and Practice of Surgery, Clinical Surgery, and Midwifery), November, 1880. Degree of M.B. or M.C., November, 1880. Part of the period of medical study is thus spent in Cambridge, and part (say after the second examination) in London or elsewhere.

---

* If he have taken the higher honours in the Natural Science School he may go in for the first M.B. examination on the first opportunity, and so have a longer period of practical study before the second M.B. examination.

† Regius Professor of Medicine—H. W. Acland, M.D., LL.D., F.R.S.
Professor of Geometry—H. S. Smith, M.A., F.R.S.
Professor of Natural Philosophy—Rev. B. Price, M.A., F.R.S.
Professor of Experimental Physics—S. Clifton, M.A., F.R.S.
Linacre Professor of Physiology—G. Rolleston, M.D., F.R.S.
Professor of Chemistry—W. Odling, M.A., F.R.S.
Professor of Zoology—J. O. Westwood, M.A.; F.L.S.
Professor of Botany—M. Lawson, M.A.
Professor of Mineralogy—N. S. Maskelyne, M.A., F.R.S.
Lee's Reader in Anatomy—J. B. Thompson, B.A.
Demonstrator in Anatomy—Charles Robertson, Esq.
Demonstrator of Chemistry—T. H. G. Wyndham, M.A.
Analyst in Health Laboratory—W. F. Donkin, M.A.

* For an account of the Scholarships see THE LANCET of the 12th of April, 1862; and for an account of the Scholarships for Natural Science see *Nature* in the early part of each year. Further information may be obtained by application to the tutor of either of the Colleges.

This University now grants degrees in State Medicine.

Attendance at the hospital and on the lectures on Anatomy, Chemistry, &c., is recognised by the Universities of Cambridge and London, and by the College of Surgeons.

The students usually remain in Cambridge during part of the long vacation (July and August) and part of the Christmas vacation, as well as during the terms.

UNIVERSITY OF LONDON.

The *Preliminary Scientific (M.B.) Examination* takes place once in each year, commencing on the third Monday in July. The candidate must have completed his seventeenth year, and have either passed the Matriculation examination or taken degree in Arts in either of the universities of Sydney, Melbourne, Calcutta, or Madras. Fourteen days' notice of his intention to present himself must be given to the registrar previous to the examination. Candidates are examined in the following subjects: Mechanical and Natural Philosophy; Inorganic Chemistry; Botany and Vegetable Physiology; Zoology. Candidates will not be approved by the examiners unless they show a competent knowledge in all the subjects of examination, and also in Practical Chemistry. Fee for this examination, £5.

Any candidate who has passed the Preliminary Scientific (M.B.)Examination may be examined for honours in Experimental Physics, Chemistry, Botany and Zoology. These examinations will commence in the second week after the Pass Examination.

The *First M.B. Examination* takes place once in each year, commencing on the last Monday in July.

A candidate is admitted to this examination on producing the following certificates:—1. Of having completed his nineteenth year. 2. Of having passed the Preliminary Scientific Examination at least one year previously.* 3. That subsequently to having taken a degree in Arts or passed the Matriculation Examination he has been a student during two years at one or more of the medical institutions or schools recognised by this University; and that he has attended a course of lectures on each of three of the subjects in the following list: Descriptive and Surgical Anatomy, General Anatomy and Physiology, Comparative Anatomy, Pathological Anatomy, Materia Medica and Pharmacy, General Pathology, General Therapeutics, Forensic Medicine, Hygiene, Obstetric Medicine and Diseases peculiar to Women and Infants, Surgery, Medicine. 4. That subsequently to having taken a degree in Arts or passed the Matriculation Examination he has dissected during two winter sessions. 5. That subsequently to having taken a degree in Arts or passed the Matriculation Examination he has attended a course of Practical Chemistry, comprehending practical exercises in conducting the more important processes of General and Pharmaceutical Chemistry, in applying tests for discovering the adulteration of articles of the materia medica, and the presence and nature of poisons; and in the examination of mineral waters, animal secretions, urinary deposits, calculi, &c. 6. That he has attended to Practical Pharmacy, and acquired a practical knowledge of the preparation of medicines. These certificates must be transmitted to the registrar at least fourteen days before the commencement of the examination.

Candidates are examined in Anatomy, Physiology,* Materia Medica and Pharmaceutical Chemistry, and Organic Chemistry, partly by printed papers and partly *vivâ voce* and by experiments and demonstrations. The fee for this examination is £5. If a candidate withdraw or fail to pass the examination, the fee shall not be returned to him; but he shall be admissible to any two subsequent First M.B. Examinations without the payment of any additional fee, provided that he give notice to the registrar at least fourteen days before the commencement of the examination.

The examinations for Honours take place in the week following that in which the Pass Examination commenced. If sufficient merit be evinced, the candidates most distinguishing themselves will receive three exhibitions of £40 per annum for the next two years, payable in quarterly instalments, provided that on receiving each instalment the candidate declare his intention of presenting himself at the Second M.B. Examination within three years from the time of his passing the First M.B. Examination. Under the same circumstances, the first and second candidates in each subject receive each a gold medal of the value of £5.

The *Second M.B. Examination*† takes place once in each year, commencing on the first Monday in November.

No candidate is admitted to this examination within two academical years of the time of his passing the first examination, nor without producing certificates—1. Of having passed the First M.B. Examination. 2. That subsequently to having passed the First M.B. Examination he has attended a course of lectures on each of two of the subjects specified, and for which he had not presented certificates at that examination. 3. Of having conducted at least twenty labours. (Certificates on this subject will be received from any legally qualified practitioner in medicine.) 4. Of having attended the surgical practice of a recognised hospital or hospitals during two years, with clinical instruction and lectures on Clinical Surgery. 5. Of having attended the medical practice of a recognised hospital or hospitals during two years, with clinical instruction, and lectures on Clinical Medicine.‡ 6. Of having, subsequently to the completion of his attendance on surgical and medical hospital practice, attended to practical medicine, surgery, or obstetric medicine, with special charge of patients, in a hospital, infirmary, dispensary, or parochial union, during six months. 7. Of having acquired proficiency in Vaccination. (Certificates on this subject will be received only from the authorised vaccinators appointed by the Privy Council.)

Candidates must also produce certificates of moral character from a teacher in the last school or institution at which they have studied. These certificates must be transmitted to the registrar at least fourteen days before the examination.

Candidates are examined in General Pathology, General Therapeutics and Hygiene, Surgery, Medicine, Obstetric Medicine, and Forensic Medicine. The examinations include questions in Surgical and Medical Anatomy, Pathological Anatomy, and Pathological Chemistry; and are partly in writing and partly oral. They also include examination and report on cases of medical patients, demonstrations from specimens and preparations, practical examinations in Forensic Medicine, and on the use of instruments and apparatus, and writing prescriptions in Latin without abbreviations. The fee for this examination is £5[*]

---

* Candidates are strongly recommended by the Senate to pass the Preliminary Scientific Examination before commencing their regular medical studies.

* Any candidate is allowed, if he so prefer, to postpone his examination in Physiology from the First M.B. Examination at which he presents himself for examination in the remaining subjects until the First M.B. Examination in the next or any subsequent year; but he cannot in that case be admitted to compete for Honours on either occasion; and he cannot be admitted as a candidate at the Second M.B. Examination until after the lapse of at least twelve months from the time of his passing the examination in Physiology.

† Any candidate for the Second M.B. Examination who has passed the First M.B. Examination under the former regulations is required to have also passed the Examination in Physiology at some previous First M.B. Examination carried on under the present regulations, at which examination he is not allowed to compete for Honours.

‡ The student's attendance on the Surgical and on the Medical Hospital Practice may commence at any date after his passing the Preliminary Scientific Examination, and may be comprised either within the same or within different years; provided that in every case his attendance on Surgical and Medical Hospital Practice be continued for at least eighteen months subsequently to his passing the First M.B. Examination. Attendance during three months in the wards of a Lunatic Asylum recognised by the University, with Clinical Instruction, may be substituted for a like period of attendance on Medical Hospital Practice. The Senate regard it as highly desirable that candidates for the degree of M.B. should practically acquaint themselves with the different forms of Insanity by attendance in a Lunatic Asylum.

Any candidate who has passed the Second M.B. Examination may be examined for Honours in Medicine, Obstetric Medicine, and Forensic Medicine. These examinations commence in the week following that in which the Pass Examination commenced. If sufficient merit be evinced, the candidates who most distinguish themselves in this examination will receive respectively—in Medicine, £50 per annum for the next two years, with the style of University Scholar in Medicine; in Obstetric Medicine, £30 per annum for the next two years, with the style of University Scholar in Obstetric Medicine; in Forensic Medicine, £30 per annum for the next two years, with the style of University Scholar in Forensic Medicine. Also the first and second candidates in each of the preceding subjects will each receive a gold medal of the value of £5.

Bachelor of Surgery.—The examination for this degree takes place once a year, commencing on the Tuesday following the fourth Monday in November. A candidate is admitted to this examination on producing certificates—(1) of having passed the Second Examination for the degree of M.B. in this University; (2) of having attended a course of instruction in Operative Surgery, and having operated on the dead subject. These certificates must be transmitted to the registrar at least fourteen days before the examination begins. The examinations are conducted by means of printed papers, by *vivâ voce* interrogation, examination and report on cases of surgical patients, Surgical Anatomy, the application of surgical apparatus, and by the performance of surgical operations on the dead subject. The fee for this examination is £5.

Any candidate who has passed the B.S. Examination may be examined for Honours in Surgery on Tuesday in the week following the Pass Examination. If sufficient merit be evinced, the candidate who distinguishes himself the most will receive £50 per annum for the next two years, with the style of University Scholar in Surgery. The first and second candidates also receive a gold medal of the value of £5.

Master in Surgery.—The examination for this degree takes place once a year, commencing on the fourth Monday in November. A candidate is admitted to this examination on producing certificates—1. Of having taken the degree of B.S.[†] in this University. 2. Of having attended subsequently to taking the degree of B.S. in this University, to Clinical or Practical Surgery during two years in a hospital or medical institution recognised by this University; or to Clinical or Practical Surgery during one year in a hospital or medical institution recognised by this University, and of having been engaged during three years in the practice of his profession; or of having been engaged during five years in the practice of his profession, either before or after taking the degree of B.S. in this University.[‡] 3. Of moral character, signed by two persons of respectability. These certificates must be transmitted to the registrar at least fourteen days before the examination begins. Candidates are examined in Logic and Moral Philosophy,[||] and in Surgery. The examination is conducted by means of printed papers and *vivâ voce* examination, as well as by dissection and the performance of surgical operations. The fee for this degree is £5.

If sufficient merit be evinced, the candidate who distinguishes himself the most in Surgery will receive a gold medal of the value of £20.

Doctor of Medicine.—The examination for this degree takes place once a year, commencing on the fourth Monday in November.

A candidate is admitted to this examination on producing certificates to the following effect:—1. Of having taken the degree of M.B. in this University. 2. Of having attended, subsequently to taking the degree of M.B. in this University, (*a*) to Clinical or Practical Medicine during two years in a hospital or medical institution recognised by this University; (*b*) or to Clinical or Practical Medicine during one year in a hospital or medical institution recognised by this University, and of having been engaged during three years in the practice of his profession; (*c*) or of having been engaged during five years in the practice of his profession either before or after taking the degree of M.B. in the University. One year of attendance on Clinical or Practical Medicine, or two years of practice, is dispensed with in the case of those candidates who at the second examination were placed in the first division. 3. Of moral character, signed by two persons of respectability.

The certificates to be transmitted to the registrar at least fourteen days before the examination. Candidates are examined in Logic and Moral Philosophy, and in Medicine. The fee for this degree is £5, excepting to such as, having taken their M.B. degree under the former regulations, shall not have paid the fee of £5 at the Preliminary Scientific Examination, and to whom therefore the fee for the M.D. degree is still £10. If sufficient merit be evinced, the candidate who distinguishes himself the most in Medicine shall receive a gold medal of the value of £20.

UNIVERSITY OF DURHAM.

Registration and Examination.—The name of every student in Medicine is placed on a register kept by the registrar of the University; and every student who has thus been registered is regarded as a matriculated student of the University in the Faculty of Medicine, receiving a certificate of his registration, for which he has to pay 5*s*.

The Registration Examination at Durham is held twice a year: shortly before the winter session, and shortly before the summer session, of the University College of Medicine, Newcastle-upon-Tyne. Every candidate for the Registration Examination must send in his name, one month at least before the day of examination, to A. Beanlands, Esq., Durham, and pay at the same time a fee of £1.

One of the University Medical Scholarships, value £25 per annum, tenable for four years, will be awarded after examination, commencing on Wednesday, the 13th of October.

The following examinations are accepted as qualifications for registration:—Durham Senior and Junior Examinations of persons not members of the University; Durham Examination for Students in Arts in their first year.

Students who matriculate are enabled to proceed to a licence in Medicine, and then to the degrees of M.B., M.D., and M.C.

Licence and Degrees.—No grace for a *Licence in Medicine* will be granted unless the petitioner is of the age of twenty-one years, has since his registration spent four years in medical study at one or more of the schools recognised by the licensing bodies named in Schedule A of the Medical Act of 1858 (one of the said four years having been spent at the University's College of Medicine, Newcastle-on-Tyne), and has passed two public examinations. No one will be admitted to the *first* of these examinations unless he has spent two years, nor to the *second* unless he has spent four years, at least, in medical study as above prescribed, and has passed the first examination; and no one will be admitted to either of these examinations unless he has produced satisfactory testimonials of conduct, and such certificates of attendance on lectures and hospital practice as the Warden and Senate shall require.

No grace for a degree of *Bachelor in Medicine* will be granted unless the petitioner is of the standing of three terms at least as a Licentiate in Medicine, and of eighteen terms (six years) at least from the date of his registration or matriculation. No one who is not a Bachelor of Arts will be admitted to the degree of Bachelor of Medicine unless he has kept one year's residence in Arts either at Durham, in the University, or at Newcastle-upon-Tyne, in the Durham University College of Medicine, and has passed both the final examination for the degree of Bachelor of

---

[*] *The Senate desire it to be understood that Bachelors of Medicine of the University of London have no right, as such, to assume the title of "Doctor of Medicine."*

[†] Candidates who have taken the degree of Bachelor of Medicine previously to 1866 will be admitted to the examination for the degree of Master in Surgery without having taken the degree of Bachelor of Surgery; and in the case of such candidates the attendance on surgical practice may commence from the date of the M.B degree.

[‡] One year of attendance on Clinical or Practical Surgery, or two years of practice, is dispensed with in the case of those candidates who at the B.S. examination were placed in the first division.

[||] Any candidate who has taken the degree either of B.A. or B.Sc. in this University is exempted from this part of the examination; and any candidate who has passed the second M.B. examination may at any subsequent M.S. or M.D. examination present himself for Logic and Moral Philosophy alone, if he so prefer; thereby gaining exemption, if he should pass, from an examination in that subject when he presents himself to be examined for the degree of Master in Surgery or Doctor of Medicine.

Arts, or an equivalent to it, and also the examination for the degree of Bachelor of Medicine.

No grace for the degree of *Doctor of Medicine* will be granted unless the petitioner is a Bachelor of Medicine of the standing of twenty-one terms (seven years) at least from his registration or matriculation, and of three terms at least from his admission to the degree of Bachelor of Medicine, nor unless he has performed the required exercises.

No grace for a *Licence in Surgery* will be granted unless the petitioner is of the age of twenty-one years, has spent four years in medical and surgical study since his registration as a student in medicine in some one or more of the schools recognised by the licensing bodies named in Schedule A of the Medical Act of 1858 (one of the said four years having been spent at the University's College of Medicine, Newcastle-upon-Tyne), and has passed two public examinations. The first of these examinations will be the first examination appointed for students in medicine. No one will be admitted to it who has not spent two years in medical and surgical study as above prescribed. The second of these examinations will be partly the same as the second examination appointed for students in medicine, and partly in surgical subjects. No one will be admitted to it who has not spent four years at least in medical and surgical study as above prescribed, and passed the first examination. No one will be admitted to either of these examinations unless he has produced satisfactory testimonials of conduct, and such certificates of attendance on lectures and hospital practice as the Warden and Senate shall require. The second examination for a Licence in Surgery may or may not be passed at the same time with the second examination for a Licence in Medicine.

No grace for the degree of *Master in Surgery* will be granted unless the petitioner is a Licentiate in Surgery and also a Licentiate in Medicine, and is of the standing of eighteen terms (six years) at least from the date of his registration or matriculation, and of three terms at least from the date of his admission to the Licence in Surgery. No one who is not a Bachelor of Arts will be admitted to the degree of Master in Surgery unless he has kept one year's residence in Arts either at Durham, in the University, or at Newcastle-on-Tyne, in the Durham University College of Medicine, and has passed the final examination for the degree of Bachelor of Arts, or an equivalent to it, besides the examination for the degree of Master in Surgery.

The Warden and Senate have authority to arrange for students in the Faculty of Medicine an examination equivalent to that for the degree of Bachelor of Arts by substituting for the theological part of it an examination in Hippocrates, Galen, or such other ancient medical author or authors as they may think fit.

Any student in medicine who was registered before Easter term, 1868, will be entitled to be admitted to the degree of Master in Surgery on the same conditions as are required for a Licence in Surgery.

UNIVERSITY OF EDINBURGH.

The session of 1875-76 will be opened on Monday, the 1st of November, at 2 P.M., with an address by the Principal.

Three medical degrees are conferred by the University of Edinburgh—namely, Bachelor of Medicine (M.B.), Master in Surgery (C.M.), and Doctor of Medicine (M.D.). The degree of C.M. is not conferred on any person who does not also at the same time obtain the degree of M.B.

1. The preliminary branches of extra-professional education are English, Latin, Arithmetic, the elements of Mathematics, and the elements of Mechanics; and the proficiency of students in these branches is ascertained by examination prior to the commencement of their medical study.

2. No candidate is admitted to a professional examination who has not passed a satisfactory examination in at least two of the following subjects, in addition to the subjects mentioned above—Greek, French, German, Higher Mathematics, Natural Philosophy, Logic, Moral Philosophy; and the examination on these latter subjects also takes place before the candidate has entered on his medical curriculum.

3. A degree in Arts (not being an honorary degree) in any one of the universities of England, Scotland, or Ireland, or in any foreign or colonial university specially recognised for this purpose by the University Court, exempts from all preliminary examination; and an examination in Arts by any corporate body whose examination has been recognised as qualifying for entrance on medical study by resolution of the General Medical Council of the United Kingdom, provided the said examination by the said corporate body shall also be approved by the University Court, shall exempt from preliminary examination in Arts, on all subjects comprised in the said examination of the said corporate body.

4. No one is admitted to the degree of Bachelor of Medicine or Master in Surgery who has not been engaged in medical and surgical study for four years. The medical session of each year, or *annus medicus*, is constituted by at least two courses of not less than a hundred lectures each, or by one such course and two courses of not less than fifty lectures each; with the exception of the clinical courses, in which lectures are to be given at least twice a week during the prescribed periods.

5. Every candidate for the degree of M.B. and C.M. must give sufficient evidence by certificates—1. That he has studied each of the following departments of medical science—viz., Anatomy, Chemistry, Materia Medica, Institutes of Medicine or Physiology, Practice of Medicine, Surgery, Midwifery and the Diseases peculiar to Women and Children, and General Pathology, each during courses including not less than one hundred lectures; Practical Anatomy, six months; Practical Chemistry, three months; Practical Midwifery, three months; Clinical Medicine and Clinical Surgery, each during courses of six months; Medical Jurisprudence, Botany, Natural History (including Zoology), during courses including not less than fifty lectures. 2. That he has attended, for at least two years, the medical and surgical practice of a general hospital which accommodates not fewer than eighty patients, and possesses a distinct staff of physicians and surgeons. 3. That he has been engaged, for at least three months, by apprenticeship or otherwise, in compounding and dispensing drugs. 4. That he has attended, for at least six months, by apprenticeship or otherwise, the out-practice of a hospital, or the practice of a dispensary, physician, surgeon, or member of the London or Dublin Society of Apothecaries.

6. The studies of candidates for the degrees of Bachelor of Medicine and Master in Surgery are subject to the following regulations:—1. One of the four years of medical and surgical study required by Section 4 must be in the University of Edinburgh. 2. Another of such four years must be either in the University of Edinburgh or in some other university entitled to give the degree of M.D. 3. Attendance during at least six winter months on the medical or surgical practice of a general hospital which accommodates at least eighty patients, and, during the same period, on a course of Practical Anatomy, may be reckoned as one of such four years. 4. One year's attendance on lectures in the hospital schools of London, or in the school of the College of Surgeons in Dublin, or of such teachers of medicine in Edinburgh, or elsewhere, as shall from time to time be recognised by the University Court, may be reckoned as one of such four years. 5. Candidates may, to the extent of four of the departments of medical study required by Section 5, sub-section 1, attend, in such year or years of their medical and surgical studies as may be most convenient to them, the lectures of teachers of medicine above specified. 6. All candidates, not students of the University, availing themselves of the permission to attend the lectures of extra-academical teachers in Edinburgh, must, at the commencement of each year of such attendance, enrol their names in a book to be kept by the University for that purpose on payment of the corresponding matriculation fee.

7. Every candidate must deliver, before the 31st day of March of the year in which he proposes to graduate, to the Dean of the Faculty of Medicine—1. A declaration, in his own handwriting, that he has completed his twenty-first year, or that he shall have done so on or before the day of graduation, and that he will not be on the day of graduation under articles of apprenticeship to any surgeon or other master. 2. A statement of his studies, as well in Literature and Philosophy as in Medicine, accompanied by proper certificates.

8. Each candidate is examined both in writing and *vivâ voce*—1st, on Chemistry, Botany, and Natural History; 2nd, on Anatomy, Institutes of Medicine, Materia Medica including Practical Pharmacy, and Pathology; 3rd, on Sur-

gery, Practice of Medicine, Midwifery, and Medical Jurisprudence; 4th, clinically on Medicine and on Surgery in a hospital.

9. Students who are ready to submit to an examination on the first division of these subjects at the end of their second year may be admitted to examination at that time.

10. Students who have passed their examination on the first division of these subjects may be admitted to examination on the second division at the end of their third year.

11. The examination on the third and fourth divisions cannot take place until the candidate has completed his fourth *annus medicus*.

12. Candidates may be admitted to examination on the first two of these divisions at the end of their third year, or to the four examinations at the end of their fourth year.

13. Candidates at these examinations found unqualified cannot be again admitted to examination unless they have studied during another year two of the prescribed subjects, either in the University or in some other school of medicine.

14. After the candidate has satisfied the medical examiners, he will be admitted on the 1st day of August, or, if that day be Sunday, then on the following day, to the degree.

15. The degree of Doctor of Medicine may be conferred on any candidate who has obtained the degree of Bachelor of Medicine, and is of the age of twenty-four years, and has been engaged, subsequently to his having received the degree of Bachelor of Medicine, for at least two years in attendance on a hospital, or the Military or Naval Medical Service, or in medical and surgical practice; provided always that the degree of Doctor of Medicine shall not be conferred on any person unless he be a graduate in Arts of one of the universities of England, Scotland, or Ireland, or of such other universities as are above specified, or unless he shall, before or at the time of his obtaining the degree of Bachelor of Medicine, or thereafter, have passed a satisfactory examination in Greek, and in Logic or Moral Philosophy, and in one at least of the following subjects—namely, French, German, Higher Mathematics, and Natural Philosophy; and provided also that the candidate for the degree of Doctor in Medicine shall, on or before the 30th day of April in the year in which he proposes to graduate, submit to the Medical Faculty a thesis, certified by him to have been composed by himself, and which shall be approved by the Faculty, on any branch of knowledge comprised in the professional examinations for the degree of Bachelor of Medicine which he may have made a subject of study after having received that degree. No thesis will be approved by the Medical Faculty which does not contain either the results of original observations in Practical Medicine, Surgery, Midwifery, or some of the sciences embraced in the curriculum for the Bachelor's degree; or else a full digest and critical exposition of the opinions and researches of others on the subject selected by the candidate, accompanied by precise references to the publications quoted, so that due verification may be facilitated. Those who have, under former regulations, given in theses when taking the degree of M.B. require no theses for M.D.

Each candidate for a degree in Medicine must produce at his final examination a certificate from a dispensary, or other public institution where vaccination is practised, attesting that he has been practically instructed in the operation, and is acquainted with the appearances which follow its performance.

Notices to Candidates for Degrees.—Candidates who commenced their medical studies by attendance on qualifying classes before February 4th, 1861, are entitled to appear for examination for the degree of Doctor of Medicine after four years' study, on completing their twenty-first year, and without having taken the degree of Bachelor of Medicine. They are also exempted from the preliminary examinations mentioned in sects. 1 and 2, and require only to undergo an examination in Latin. They are also exempted from attendance on Practical Chemistry and Practical Midwifery, and require only three months of Clinical Surgery and eighteen months of hospital attendance.

An *annus medicus* is constituted by at least two winter courses of 100 lectures each, or by one such course and two summer courses of 50 lectures each, all being duly certified.

Four *anni medici* are required for graduates in Medicine. Two at least of these years must be passed at a university which grants degrees in Medicine, one of the two being at Edinburgh. One or two of the *anni medici* may be taken at qualified extra-academical schools. In University College, in King's College, in the hospital schools of London, in the extra-academical schools of Edinburgh, in the school of the College of Surgeons of Dublin, and in certain medical schools where at least two lecturers have been qualified by the University Court, a candidate may make two *anni medici*—one of which must be constituted by hospital attendance and Practical Anatomy, the other by at least two courses of 100 lectures, or one such course and two courses of fifty lectures. The classes at these schools only qualify to the extent of four, and one of the four must be Practical Anatomy. In provincial schools, where there are no lecturers qualified by the University Court, a candidate can make one *annus medicus* only, and this is constituted by attendance on a qualified hospital, along with a course of Practical Anatomy.

The Edinburgh extra-academical classes only qualify if the fee paid at the commencement of the session is the same as that paid to the professors in the University.

All the classes mentioned must be taken at a university, except the four selected by the candidate; and those so selected must be qualifying courses as regards subjects and extent.

Three months' courses of Materia Medica, Pathology, and Midwifery do not qualify. For each of these subjects one course of 100 lectures is required.

Every candidate for a degree in Medicine must be a matriculated student of the University for the year in which he appears for examination or graduation.

Specimens of the examination papers for 1874–75 are given in the Calendar.

Candidates who appear for examination must produce certificates of having attended *complete* courses of the subjects on which they are to be examined.

Candidates, settled for a period of years in foreign parts, who have complied with all the regulations for the degree of M.D., but who cannot appear personally to receive the degree, may, on satisfying the Senatus to that effect, by production of sufficient official testimonials, have the degree conferred on them in absence.

The fees for examination are: For the Preliminary Examination each non-matriculated student pays a fee of 10*s.* (this fee allows the candidate to appear at the Preliminary Examination during one academic year); for the degree of M.B., three examinations, £5 5*s.* each (£15 15*s.*); for the degree of C.M., £5 5*s.* additional; for the degree of M.D., £5 5*s.* additional to that for M.B., exclusive of £10 Government stamp. The graduation fees must all be paid on or before the 15th July in the year in which candidates propose to graduate.

UNIVERSITY OF GLASGOW.

Three degrees in Medicine are granted—viz., Bachelor of Medicine, Master in Surgery, and Doctor of Medicine. The curricula of study and the examinations for the several degrees conferred are nearly the same as in the University of Edinburgh. The annual terms for conferring medical and surgical degrees are the 1st May and the 1st August. The Preliminary Examinations of medical students in branches of general education take place on the 8th October, 1875, and on the 2nd April, 1876.

The fees for the degrees are as follows:—For the degree of M.B. (for each of three examinations, £5 5*s.*) £15 15*s.*; for that of C.M. (in addition to the fee of M.B.), £5 5*s.*; for the M.D. (in addition to the fee for M.B.), £5 5*s.*; and Government stamp for diploma, £10 3*s.*

The regulations under which the above degrees are granted and the notices of the subjects of examination, may be obtained by application to the registrar of the University.

Bursaries tenable by Medical Students.—The Brisbane Bursary, of £50 yearly, held for four years by a student of medicine who is a Master of Arts. The Walton Bursary, of £36 yearly, held by a medical student (a native of England being preferred) for four years. The Logan Bursary, of £16 yearly, tenable by a medical student for four years. Two Rainy Bursaries, value £20 per annum each, open to medical students who have just completed the second year of professional study, and tenable for two years. The Armagh Bursaries, three in number, amounting each to £25 yearly, for three years, open to students of Divinity, Law, and Medicine, who have taken the degree of M.A. The Macfarlane

Bursary, value £40 per annum, and tenable for three years, open to students who have attended the first session of their professional study in the University of Glasgow, and who have passed in all the seven subjects of the Preliminary Examination for M.B.

UNIVERSITY OF ABERDEEN.

The curricula for the several degrees conferred are nearly the same as in the University of Edinburgh.

Professional Examinations will be held twice in each year—namely, in April and July, directly after the close of the winter and summer sessions.

The fees for graduation are the same as in the University of Edinburgh. Matriculation fee, including all dues, for the winter and summer sessions, £1; summer session alone, 10*s*.

Candidates who commenced their medical studies before November, 1861, are entitled to appear for examination for the degree of M.D. after four years' study, one of which must have been in the University of Aberdeen.

Besides the Royal Infirmary, students have the opportunity of attending the following institutions:—General Dispensary, and Lying-in and Vaccine Institutions: daily. Royal Lunatic Asylum: Clinical instruction is given for three months in the year. Eye Institution: Clinical instruction is given on the Diseases of the Eye, and on the application of the Ophthalmoscope for their diagnosis.

Application for further information should be addressed to Professor Brazier, Secretary of the Medical Faculty.

UNIVERSITY OF ST. ANDREWS.

Three degrees of Medicine are granted—namely, Bachelor of Medicine (M.B.), Master in Surgery (C.M.), and Doctor of Medicine (M.D. The curricula for these degrees, and the regulations under which they are conferred, differ from those of the University of Edinburgh only in the particulars noticed below.

The degree of *Doctor of Medicine* may be conferred by the University of St. Andrews on any registered medical practitioner above the age of forty years whose professional position and experience are such as, in the estimation of the University, to entitle him to that degree, and who shall, on examination, satisfy the medical examiners of the sufficiency of his professional knowledge; provided always, that degrees will not be conferred, under this section, to a greater number than ten in any one year. The examinations are held yearly, towards the end of April. Candidates must lodge with the Dean of the Medical Faculty the following certificates along with application for admission to examination:—1. A certificate of age, being a baptismal certificate or an affidavit of age. 2. Holograph certificates from at least three medical men of acknowledged reputation in the medical profession or in the medical schools, recommending the candidate to the Senatus for the degree, and testifying to his professional skill and position. As only ten can graduate yearly, candidates will be selected whose service and certificates seem to the Medical Faculty to present the highest professional claims, and where these seem equal, preference will be given to age and priority of application. 3. Candidates, when notified for examination, shall remit a portion of the graduation fee (viz., £15 15*s.*) This sum shall be forfeited should the candidate fail to appear, or to graduate, at the time appointed. 4. A satisfactory examination, written and *vivâ voce*, must be passed in the following departments—viz., Materia Medica and General Therapeutics, Medical Jurisprudence, Practice of Medicine and Pathology, Surgery, Midwifery and Diseases of Women and Children.

No one will be received as a candidate for the degree of *Bachelor of Medicine* or *Master in Surgery* unless two years at least of his four years of medical and surgical study shall have been in one or more of the following universities or colleges—viz., the Universities of St. Andrews, Glasgow, Aberdeen, Edinburgh, Oxford, and Cambridge; Trinity College, Dublin; Queen's College, Belfast; Queen's College, Cork; and Queen's College, Galway.

Subject always to the condition here specified, the studies for candidates for the degrees of Bachelor of Medicine and Mastery in Surgery will be under the following regulations: The remaining years of medical and surgical study may be either in one or more of the universities and colleges above specified, or in the hospital schools of London, or in the school of the College of Surgeons in Dublin, or under such private teachers of medicine as may from time to time receive recognition from the University Court. Attendance during at least six winter months on the medical or surgical practice of a general hospital which accommodates at least eighty patients, and during the same period on a course of Practical Anatomy, may be reckoned as one of such remaining years. Attendance on the lectures of any private teacher in Edinburgh, Glasgow, or Aberdeen, will not be reckoned for graduation in St. Andrews, if the fee for such lectures be of less amount than is charged for the like course of lectures in the University of Edinburgh, of Glasgow, or of Aberdeen, according as the teacher lectures in those places respectively.

Every candidate for examination for the degree of M.B. and C.M. is required to lodge a declaration of age, a statement of his course of study, his inaugural dissertation, and all his certificates, with the Dean of the Medical Faculty, on or before the 25th of March in each year.

No candidate offering himself for examination on the first two divisions of the subjects specified in Clause 12 of the Regulations will be considered to have passed in the second if he fails in the first; and no candidate offering himself for examination on the three divisions shall be considered to have passed in the third if he fails either in the first or second division.

Every candidate who fails to pass in any of the divisions will, for a first failure, in any and each of the divisions, forfeit the sum of £2 2*s.*, and £1 1*s.* for every subsequent failure in each.

UNIVERSITY OF DUBLIN (TRINITY COLLEGE).

Matriculation.—All students of the School of Physic intending to practise Physic must be matriculated, for which a fee of 5*s.* is payable. No student can be admitted for the winter courses after Nov. 25th.

Previous Medical Examination.—Candidates for degrees and licences in Medicine and Surgery are required to pass a previous examination in Physics, Chemistry, Botany, Materia Medica and Pharmacy, and Descriptive Anatomy, previous to their degree examination.

Bachelor in Medicine.—A candidate for the degree of Bachelor in Medicine must be a graduate in Arts, and may obtain the degree of Bachelor in Medicine at the same commencement as that at which he receives his degree of B.A., or at any subsequent commencement. The medical education of a Bachelor in Medicine is of four years' duration, and comprises attendance on a single course of each of the following lectures:—Anatomy, Practical Anatomy, Surgery, Chemistry, Materia Medica and Pharmacy, Institutes of Medicine, Practice of Medicine, Midwifery, Botany, Medical Jurisprudence, Heat, Electricity, Magnetism, Comparative Anatomy. Three courses of nine months' attendance on the clinical lectures of Sir Patrick Dun's or other metropolitan hospital recognised by the Board of Trinity College. Six months' instruction in Practical Midwifery, including Clinical Lectures. A certificate of personal attendance on Fever cases, with names and dates of cases. Six months' Dissections are required. Three months' Laboratory instruction in Chemistry is required. Any of the above-named courses may be attended at any medical school in Dublin recognised by the Provost and senior Fellows. The fee for the *Liceat ad Examinandum* is £5; for the M.B. degree, £11.

Doctor in Medicine.—A Doctor in Medicine must be M.B. of at least three years' standing, or have been qualified to take the degree of M.B. for three years, and must perform exercises for the degree before the Regius Professor of Physic, in accordance with the rules and statutes of the University. Total amount of fees for this degree, £13.

Bachelor in Surgery.—A Bachelor in Surgery must be a Bachelor in Arts, and have spent four years in the study of Surgery and Anatomy. He must also pass a public examination in the Hall before the Professors of the School of Physic, having previously completed the prescribed curriculum of study.*

---

* Students in the School of Physic who matriculated before June 22nd, 1872, may obtain the degree of Master in Surgery, according to the regulations in force previous to the creation of the degree of Bachelor in Surgery.

Candidates are required to perform surgical operations on the dead subject.

Candidates for the degree of Bachelor in Surgery, who have already passed the examination for the degree of Bachelor in Medicine, will be examined in Anatomy and Surgery only.

Fee for the *Liceat ad Examinandum*, £5; fee for the degree of Bachelor in Surgery, £1.

*Master in Surgery.** — A Master in Surgery must be a Bachelor in Surgery of three years' standing, or have been qualified to take the degree of Bachelor in Surgery for three years; and must read two theses publicly before the Regius Professor of Surgery, or undergo an examination before the Regius Professor, according to regulations to be approved by the Provost and Senior Fellows.

Fee for the degree of Master in Surgery, £11.

University Licences.—Candidates for the Licences in Medicine or Surgery must be matriculated in Medicine, and must have completed two years in Arts and four years in medical studies.

Licentiate in Medicine.—The medical course and examination necessary for the Licence in Medicine are the same as for the degree of M.B.

A Licentiate in Medicine, on completing his course in Arts, and proceeding to the degree of B.A., may become a Bachelor in Medicine, on paying the degree fees, without further examination in Medicine. Fee for the *Liceat ad Examinandum*, £5; for the Licence in Medicine, £5.

Licentiate in Surgery.—The surgical course and examination necessary for the Licence in Surgery are the same as for the degree of Bachelor in Surgery. Fee for the *Liceat ad Examinandum*, £5; for the Licence in Surgery, £5.

Medical Scholarships.—Two Medical Scholarships will be given annually, tenable for two years, with a salary of £20 per annum, on the condition of the successful candidates proceeding regularly for two years with the medical course in the University.

Qualification in State Medicine.—Doctors in Medicine of Dublin, Oxford, or Cambridge, who wish to obtain from the University a Certificate of Qualification in State Medicine, can do so on passing an examination in a limited course of the following subjects:—1. Law, comprehending sanitary legislation and the laws relating to the conduct and duties of medical men. 2. Engineering in its sanitary aspects. 3. Pathology, including the laws of epidemics, vaccination, insanity, &c. 4. Vital and sanitary statistics. 5. Chemistry in relation to air, water, gaseous poisons, deodorisation, and disinfection. 6. Meteorology. 7. Medical Jurisprudence.

The total cost of the education and first degrees in Medicine and Surgery is as follows, in addition to the fees for education in Arts and B.A. degree (£83 4*s*); Medical and Surgical Lectures, £52 15*s.*; Hospitals, £33 12*s.*; Medical and Surgical Examinations and Degrees, £22.

THE QUEEN'S UNIVERSITY IN IRELAND.

Granting the degrees of *Doctor in Medicine* and *Master in Surgery*, and diplomas in Midwifery, includes three Colleges—the Queen's Colleges of Belfast, Cork, and Galway—each of which possesses a Faculty of Medicine. The curriculum of medical study extends over a period of four years, and is divided into two periods of two years each. The first period comprises attendance on Chemistry, Natural History, Anatomy and Physiology, Practical Anatomy, Materia Medica and Pharmacy. The second period comprises attendance on Anatomy and Physiology, Practical Anatomy, Theory and Practice of Surgery, Midwifery and Diseases of Women and Children, Theory and Practice of Medicine, and Medical Jurisprudence. At least two of the above courses of lectures must be attended in some one of the Queen's Colleges; the remainder may be taken, at the option of the candidate, in any university, college, or school recognised by the Senate of the Queen's University. Candidates are required to have also attended, in one of the Colleges of the Queen's University, lectures on Experimental Physics and on one Modern Language, and to have passed the Matriculation Examination. They are further required to attend, during the first period, Practical Chemistry in a recognised laboratory, and the practice during six months of a recognised medico-chirurgical hospital, containing at least sixty beds, together with the clinical lectures delivered therein; and to attend, during the second period, a recognised midwifery hospital, with the clinical lectures therein delivered, for a period of three months; or a midwifery dispensary for the same period; or ten cases of labour, under the superintendence of the medical officer of any hospital or dispensary where cases of labour are treated; and eighteen months' practice of a recognised medico-chirurgical hospital containing at least sixty beds, and in which clinical instruction is delivered. There are three University Examinations: the First University Examination, the Second University Examination, and the Degree Examination. The degree of Master in Surgery and the diploma in Midwifery are only conferred upon candidates who already hold the degree of Doctor in Medicine, and who have also passed a special examination in surgery or medicine. The University Examinations are held twice in each year—in June and September. Candidates who commence their medical studies elsewhere are admitted to the First University Examination before proceeding to College. Further information will be found in the "Queen's University Calendar," or may be obtained by application to the Secretary, Queen's University, Dublin Castle.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

Members.—1. The members of the College, present and future, shall be alone eligible to the fellowship. They shall have the use of the library and museum, and shall be admitted to all lectures.

2. All persons who have been admitted before Feb. 16th, 1859, licentiates of the College, shall be entitled to be admitted members of the College, provided that they have, since their admission as licentiates, obeyed the bye-laws.

3. Any extra-licentiate who shall have produced testimonials as to character satisfactory to the Censors, and shall have assured the said Censors that he is not engaged in the practice of pharmacy, and who shall comply with the bye-laws, may be proposed to the College to be admitted a member of the College.

4. Any person who shall have satisfied the College touching his acquirements in general science and literature, and his knowledge of Medicine, Surgery, and Midwifery, and who shall comply with the bye-laws, may be proposed to be admitted a member of the College.

5. Every candidate for the membership of the College under the last bye-law, who shall have commenced his professional studies after September, 1861, shall satisfy the Censors' Board that, previous to the commencement of his professional studies, he has obtained a degree in Arts from some university of the United Kingdom or of the colonies, or from some other university specially recognised by the Medical Council, or that he has passed examinations equivalent to those required for a degree in Arts. All other candidates for membership shall be examined on the subjects of general education by the President and Censors of the College.

6. Every candidate for membership shall furnish proof that he has attained the age of twenty-five years.

7. Every candidate shall produce a testimonial from a fellow or member of the College, satisfactory to the Censors' Board, to the effect that, as regards moral character and conduct, he is a fit and proper person to be admitted a member of the College.

8. Every candidate (except such as shall be admissible under the provisions of sections 15 and 16) shall produce proof of his having been engaged in professional studies during a period of five years, of which four years at least shall have been passed at a medical school or schools recognised by the College.

9. Every candidate (except such as shall be admissible under the provisions of Sections 15 and 16) shall produce evidence, satisfactory to the Censors' Board, of his having studied the following subjects: — Anatomy (with Dissections) and Physiology, during two winter sessions; Chemistry, six months; Practical Chemistry, Materia Medica, Practical Pharmacy, and Botany, three months each; Morbid Anatomy, six months; Principles and Practice of Medicine and Principles and Practice of Surgery, during two winter sessions; Clinical Medicine during three

---

* N.B.—After the year 1874, Masters in Surgery must be of the standing of Masters in Arts.

winter sessions and three summer sessions; Clinical Surgery, two winter and two summer sessions; Midwifery and the Diseases peculiar to Women, and Forensic Medicine, three months each. Of having attended diligently during three winter and three summer sessions the medical practice, and during three winter and two summer sessions the surgical practice, of a hospital containing at least 100 beds. Of having been engaged during six months in the clinical study of diseases peculiar to women; and of having served the office of clinical clerk in the medical wards during at least six months.

10. Every candidate who has prosecuted his studies abroad, whether in part or to the full extent required by the preceding bye-law (except such as shall be admissible under the provisions of Section 16), shall, nevertheless, bring proof of his having attended during at least twelve months the medical practice of a hospital in the United Kingdom containing at least 100 beds.

11. If the Censors' Board doubt the sufficiency of the certificates and testimonials produced by any candidate, or his fitness in any respect for admission to examination, they may submit the case to a general meeting of the Fellows.

12. No candidate shall be admitted to examination who is engaged in trade, or who dispenses medicine, or makes any engagement with a chemist or any other person for the supply of medicines; or who practises medicine or surgery in partnership, by deed or otherwise, so long as that partnership continues.

13. No candidate shall be admitted to examination who refuses to make known, when required by the President and Censors, the nature and composition of any remedy he uses.

14. Every candidate (except in cases specially exempted under Sections 15 and 16) shall give proof of his acquirements by written answers to questions placed before him, and shall be examined *vivâ voce* at three separate examinations, and shall be approved by the President and Censors, or by the major part of them. The First Examination, on Anatomy and Physiology, will be conducted by written questions, and also *vivâ voce*, on Dissections and Preparations. The Second Examination will comprise Surgical Anatomy, Principles and Practice of Surgery, Materia Medica, Chemistry in its application to Pathology, Pharmacy and Toxicology, Midwifery and Diseases peculiar to Women. This examination will be conducted partly by written questions, and partly in a practical manner. The Third or Pass Examination will include Medical Anatomy, Principles and Practice of Medicine (including the Principles of Public Health), and Psychological Medicine.

Examinations of candidates for the Membership of the College will take place in January, April, July, and October, further particulars of which, if needed, can be obtained on application at the College.

Candidates will not be admitted to the First Examination until after the termination of the second winter session of professional study at a recognised medical school, nor to the Second Examination until after the termination of four years of professional study, nor to the Third or Pass Examination until after the completion of the required course of professional study. Any candidate who shall be rejected at the First Examination will not be readmitted to examination until after the lapse of three months, and will be required to produce a certificate of the performance of dissections, or other professional study satisfactory to the examiners, during that time. Any candidate who shall be rejected at the Second Examination will not be readmitted to examination until after the lapse of three months, and will be required to produce a certificate of attendance on the practice of a recognised hospital during that time, and also of attendance on clinical lectures. Any candidate not approved by the Censors' Board at the Third or Pass Examination will not (except by special permission of the College) be readmitted to examination until after the lapse of a year. Every candidate must give fourteen days' notice in writing to the Registrar of the College of his intention to present himself for examination, at the same time transmitting the following certificates:—For the Primary Examination: Evidence of having passed an Arts Examination; of having been duly registered as a medical student; and of having completed the second winter session of professional study at a recognised medical school. For the Second Examination: Evidence of having completed four years of professional study; of having attained the age of twenty-one years; of instruction and proficiency in the practice of Vaccination; and of having attended not less than twenty labours. For the Pass Examination: Proof of having attained the age of twenty-five years; a testimonial from a fellow or member of the College; evidence of having completed the required course of professional study.

15. Any candidate who has already obtained the degree of Doctor or Bachelor of Medicine at a university in the United Kingdom, wherein the courses of study and the examinations to be undergone by the students previously to graduations shall have been adjudged by the Censors' Board to be entirely satisfactory, shall be exempt (if the Censors shall think fit) from all or any parts of the examinations hereinbefore described, except such as relate to the Third or Pass Examination; the nature and extent of which examination shall, in the case of each candidate, be determined by the Censors' Board. Every candidate for the membership will, however, be required to translate into English a passage from a Latin author, and he will have the opportunity of showing a knowledge of Greek, or of one or more of the modern European languages.

16. If any candidate who has attained the age of forty years shall produce testimonials not merely satisfactory as to his moral character and conduct, and his general and professional acquirements, but further showing that he has improved the art or extended the science of medicine, or has at least distinguished himself highly as a medical practitioner, the Censors' Board, having well weighed and considered these testimonials, may, if they see fit, submit them to the Fellows at a general meeting, and it shall be determined by the votes of the Fellows present, or of the majority of them, taken by ballot, whether the candidate shall be admitted to examination, which shall, in every such case, be as full and complete as the Censors may deem sufficient.

17. Any candidate who shall produce satisfactory evidence of having passed an examination in Anatomy and Physiology, conducted by any of the bodies named in Schedule A to the Medical Act, and recognised by the College as requiring a course of study and an examination satisfactory to the College, will be exempt from re-examination on the subjects of the Primary Examination.

18. Any candidate who shall have obtained a degree in Surgery at a university in the United Kingdom, after a course of study and an examination satisfactory to the College, will be exempt from re-examination on Surgical Anatomy and the Principles and Practice of Surgery.

19. Any candidate who shall have passed the examination on Surgery conducted by the Royal College of Surgeons of England, or the Royal College of Surgeons of Edinburgh, or the Royal College of Surgeons in Ireland, after a course of study and an examination satisfactory to the College, will be exempt from re-examination on Surgical Anatomy and on the Principles and Practice of Surgery.

The fee to be paid for admission is £31 10s.

Licentiates.—The Licence of this College is a qualification to practise Medicine, Surgery, and Midwifery, and is recognised by the Poor-law Board as a qualification in Surgery as well as in Medicine. Every candidate for the College licence (except when otherwise provided by the bye-laws) is required to produce satisfactory evidence to the following effect:—1. Of having attained the age of twenty-one years. 2. Of moral character. 3. Of having passed, before the commencement of professional study, an examination in the subjects of general education recognised by the College. 4. Of having been registered as a medical student in the manner prescribed by the General Medical Council. 5. Of having been engaged in professional studies during four years, of which at least three winter sessions and two summer sessions shall have been passed at a recognised medical school or schools; and one winter session and two summer sessions in one or other of the following ways:—Attending the practice of a hospital or other institution recognised by the College for that purpose. Receiving instruction as the pupil of a legally qualified practitioner holding any public appointment which affords opportunities, satisfactory to the examiners, of imparting a practical knowledge of Medicine, Surgery, or Midwifery. Attending lectures on any of the required subjects of professional study at a recognised place of instruction. Professional studies commenced *before* the candidate shall have passed an examination in the subjects of general education will not be recognised by the College.

6. Of having attended, during three winter sessions and two summer sessions, the medical and surgical practice at a recognised hospital or hospitals; of having discharged the duties of clinical clerk at a recognised hospital for a period of not less than three months; of having performed the duties of dresser at a recognised hospital for a period of not less than three months; and of having been engaged during six months in the clinical study of Diseases peculiar to Women. 7. Of having studied the subjects particularised in Section 9 of the regulations given above relating to members. 8. Of having passed the Professional Examinations.

Examinations for the Licence.—Every candidate for the College licence, before he is admitted to examination, is required to sign a declaration stating whether he has or has not been rejected within three months by any of the examining boards.

The First and Second Examinations, and the Second or Pass Examination, embrace the same subjects, and are conducted similarly to the First and Second Examinations for the membership. The exemptions also from re-examination differ only in the following respects:—Any candidate who shall have obtained a degree in Medicine at a university recognised by the College, after a course of study, and an examination satisfactory to the College, shall be exempt from re-examination on the subjects of the Primary Examination. Any "registered medical practitioner" whose qualification or qualifications shall have been obtained before the 1st day of January, 1861, having been, with the consent of the College, admitted a candidate for the licence, will be examined on the Principles and Practice of Medicine, Surgery, and Midwifery; but he will be exempted from such other parts of the professional examinations as his qualifications may seem to the examiners to render unnecessary.

The fee for the College licence is fifteen guineas, of which five guineas are to be paid on admission to the First Examination, which fee will not be returned to any candidate rejected at this examination, but will be allowed in the fee for the licence, and he will be admitted to one subsequent First Examination without additional payment.

Any candidate who shall be rejected at the Second or Pass Examination will have the fee paid on admission to this examination returned to him, less three guineas.

Examinations of candidates for the College licence will take place in February, April, July, October, and December.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

REGULATIONS RESPECTING THE EDUCATION AND EXAMINATION OF CANDIDATES FOR THE DIPLOMA OF MEMBER.

Preliminary General Education and Examination.—Candidates who commenced their professional education on or after 1st January, 1861, will be required to produce one or other of the certificates of proficiency granted by the educational bodies specified in the recommendations of the General Medical Council (see *ante*). Candidates who shall not be able to produce one or other of those certificates will be required to pass an examination* in English, Classics, and Mathematics, conducted by the Board of Examiners of the Royal College of Preceptors, under the direction and supervision of this College.

Each candidate is required to pay a fee of £2 on the morning of the first day of the examination prior to his admission thereto. The next examination will be held on or about the third Tuesday or Wednesday in December. The exact dates of the examinations will be duly advertised, when fixed, in the medical journals; and candidates are required to send in the prescribed forms of application not less than three weeks before the examination.

Professional Education.—Professional studies prior to the date at which the candidate shall have passed an examination in general knowledge, in conformity with the preceding regulation, are not recognised.

The following will be considered as the commencement of professional education:—Attendance on the practice of a hospital or other public institution recognised by this College for that purpose. Instruction as the pupil of a legally qualified surgeon, holding the appointment of surgeon to a hospital, general dispensary, or union workhouse, or where such opportunities of practical instruction are afforded as shall be satisfactory to the Council. Attendance on lectures on Anatomy, Physiology, or Chemistry, by lecturers recognised by this College.

The commencement of professional study otherwise than by attendance on lectures in recognised medical schools, or by attendance on the practice of recognised hospitals, will not be admitted until a certificate thereof shall be furnished to the secretary for registration at the College by the practitioner whose pupil the candidate shall have become, or by the medical superintendent of the hospital or other institution to the practice of which he shall have entered, and will consequently date only from the reception of such certificate by the secretary; the certificate to be accompanied by proof of having passed the necessary preliminary examination in general knowledge.

Candidates will be required to produce the following other certificates:—1. Of being twenty-one years of age. 2. Of having been engaged, subsequently to the date of passing the Preliminary Examination, during four years, or during a period extending over not less than four winter and four summer sessions, in the acquirement of professional knowledge. 3. Of having attended lectures on Anatomy during two winter sessions. 4. Of having performed Dissections during not less than two winter sessions. 5. Of having attended lectures on General Anatomy and Physiology during one winter session. 6. Of having attended a practical course of General Anatomy and Physiology during another winter or a summer session, consisting of not less than thirty meetings of the class. 7. Of having attended lectures on Surgery during one winter session. 8. Of having attended a course of Practical Surgery during a period occupying not less than six months prior or subsequent to the course required by the preceding clause 7. 9. Of having attended one course of lectures on each of the following subjects—namely, Chemistry, Materia Medica, Medicine, Forensic Medicine, Midwifery (with practical instruction, and a certificate of having personally conducted not less than ten labours), Pathological Anatomy during not less than three months. 10. Of have studied Practical Pharmacy during three months. 11. Of having attended a three months' course of Practical Chemistry (with manipulations) in its application to medical study. 12. Of instruction and proficiency in the practice of Vaccination. 13. Of having attended at a recognised hospital or hospitals the Practice of Surgery during three winter and two summer sessions. 14. Of having been individually engaged, at least twice in each week, in the observation and examination of patients at a recognised hospital or hospitals, under the direction of a recognised teacher, during not less than three months. 15. Of having, subsequently to the first winter session of attendance on Surgical Hospital Practice, attended, at a recognised hospital or hospitals, Clinical Lectures on Surgery, during two winter and two summer sessions. 16. Of having been a Dresser at a recognised hospital, or of having, subsequently to the completion of one year's professional education, taken charge of patients under the superintendence of a surgeon during not less than six months, at a hospital, general dispensary, or parochial or union infirmary recognised for this purpose, or in such other similar manner as, in the opinion of the Council, shall afford sufficient opportunity for the acquirement of Practical Surgery. 17. Of having attended during the whole period of attendance on Surgical Hospital Practice (see Clause 13) demonstrations in the post-mortem room of a recognised hospital. 18. Of having attended, at a recognised hospital or hospitals, the Practice of Medicine, and Clinical Lectures on Medicine, during one winter and one summer session.

Blank forms of the required certificates may be obtained on application to the Secretary, and all necessary certificates will be retained at the College.

Certificates will not be received on more than one branch of science from one and the same lecturer; but Anatomy and Dissections will be considered as one branch of science.

Certificates will not be recognised from any hospital in the United Kingdom unless the surgeons thereto be members of one of the legally constituted Colleges of Surgeons in the United Kingdom; nor from any School of Anatomy and Physiology or Midwifery, unless the teachers in such school be members of some legally constituted College of Physicians or Surgeons in the United Kingdom; nor from any School of Surgery, unless the teachers in such school be members of one of the legally constituted Colleges of Surgeons in the United Kingdom.

---

* The subjects of this examination during the years 1875-76 may be obtained by application at the College.

No metropolitan hospital will be recognised by this College which contains less than 150, and no provincial or colonial hospital which contains less than 100 patients.

Certificates of attendance upon the practice of a recognised provincial or colonial hospital unconnected with, or not in convenient proximity to, a recognised medical school, will not be received for more than one winter and one summer session of the hospital attendance required by the regulations of this College; and in such cases clinical lectures will not be necessary, but a certificate of having acted as dresser for the period of at least six months will be required.

Certificates will not be received from candidates who have studied in London, unless they shall have registered at the College their cards of admission to attendance on lectures and hospital practice within fifteen days from the commencement of the session; nor from candidates who have studied in the provincial schools of England, unless their names shall be duly returned from their respective schools.

At their first registration in October, candidates will be required to produce a certificate of having passed one or other of the recognised preliminary examinations.

Those candidates who shall have pursued the whole of their studies in Scotland or Ireland will be admitted to examination upon the production of the several certificates required respectively by the College of Surgeons of Edinburgh, the Faculty of Physicians and Surgeons of Glasgow, and the College of Surgeons in Ireland, from candidates for their diploma, together with a certificate of instruction and proficiency in the practice of Vaccination, and satisfactory evidence of having been occupied, subsequently to the date of passing the Preliminary Examination, at least four entire years in the acquirement of professional knowledge; and in the case of candidates who shall have pursued the whole of their studies at recognised foreign or colonial universities, upon the production of the several certificates required for their degree by the authorities of such universities, together with a certificate of instruction and proficiency in the practice of Vaccination, and satisfactory evidence of having been occupied, subsequently to the date of passing the Preliminary Examination, at least four entire years in the acquirement of professional knowledge.

Members or licentiates of any legally-constituted College of Surgeons in the United Kingdom, and graduates in Surgery of any university recognised for this purpose by this College, will be admitted to examination on producing their diploma, licence, or degree, together with proof of being twenty-one years of age, a certificate of instruction and proficiency in the practice of Vaccination, and satisfactory evidence of having been occupied, subsequently to the date of passing the Preliminary Examination, at least four years in the acquirement of professional knowledge.

Graduates in Medicine of any legally-constituted college or university, recognised for this purpose by this College, will be admitted to examination on adducing, together with their diploma or degree, proof of being twenty-one years of age, a certificate of instruction and proficiency in the practice of Vaccination, and satisfactory evidence of having been occupied, subsequently to the date of passing the Preliminary Examination, at least four entire years in the acquirement of professional knowledge.

Professional Examination.—This examination is divided into two parts. The First or Primary Examination, on Anatomy and Physiology, is partly written and partly demonstrative on the recently dissected subject, and on prepared parts of the human body. The Second or Pass Examination, on Surgical Anatomy and the Principles and Practice of Surgery and Medicine,* is partly written, partly oral, and partly on the practical use of surgical apparatus and the practical examination of patients. The Primary Examinations are held in the months of January, April, May, July, and November, and the Pass Examinations generally in the ensuing week respectively. Candidates will not be admitted to the Primary Examination until after the termination of the second winter session of their attendance at a recognised school or schools; nor to the Pass or Surgical Examination until after the termination of the fourth year of their professional education. The fee of five guineas, paid prior to the Primary Examination, and allowed on the whole fee of £22 payable for the diploma, is retained; and after any two consecutive failures at the Primary Examination the candidate is required to pay an *additional* fee of five guineas prior to being again admitted to that examination, which *additional* fee is also retained. Five guineas, part of the sum of £16 15*s.*, the balance of the whole fee due for the diploma, and paid prior to the Pass Examination, is retained; and after any two consecutive failures at the Pass Examination the candidate is required to pay an *additional* fee of £5 5*s.* prior to being again admitted to the Pass Examination, which *additional* fee is also retained. A candidate having entered his name for either the Primary or Pass Examination, who shall fail to attend the meeting of the Court for which he shall have received a card, will not be allowed to present himself for examination within the period of three months from the date at which he shall have so failed to attend. A candidate referred on the Primary Examination is required, prior to his admission to re-examination, to produce a certificate of the performance of dissections during not less than three months, subsequently to the date of his reference. A candidate referred on the Pass Examination is required, prior to his admission to re-examination, to produce a certificate of at least six months' further attendance on the surgical practice of a recognised hospital, together with lectures on Clinical Surgery, subsequently to the date of his reference.

For the diploma of Fellow, the regulations as to the *Preliminary Examination* are very nearly the same as for the Membership.

THE CERTIFICATE OF QUALIFICATION IN MIDWIFERY.

The examinations for this certificate are held in the months of February, May, August, and December.

The fee for the certificate is as follows—namely: Persons who were fellows or members of this College prior to the 1st of January, 1853, two guineas. Persons admitted fellows or members of this College subsequently to the 1st of January, 1853, three guineas. Persons producing any other diploma or certificate of degree which may be considered by the Council to afford satisfactory proof of sufficient surgical and medical education, three guineas. All other persons, ten guineas.

THE DIPLOMA IN DENTAL SURGERY.

Examination.—The examination is partly written and partly oral. The written examination comprises General Anatomy and Physiology, and General Pathology and Surgery, with especial reference to the practice of the dental profession. The oral practical examination comprises the several subjects included in the curriculum of professional education, and is conducted by the use of preparations, casts, drawings, &c. Members of the College, in the written examination, will have to answer only those questions set by the section of the Board consisting of persons skilled in dental surgery; and in the oral examination will be examined only by that section. A candidate whose qualifications shall be found insufficient will be referred back to his studies, and will not be admitted to re-examination within the period of six months, unless the Board shall otherwise determine. Examinations will be held in January and June. The fee for the diploma is ten guineas, over and above any stamp duty.

ROYAL COLLEGE OF PHYSICIANS, EDINBURGH.

The Licence.—No one can obtain the licence of the College until he has completed the age of twenty-one years.

Every applicant for the licence must produce a certificate that he has studied Vaccination under a recognised teacher.

The Preliminary Examination in General Education prescribed by the General Medical Council must have been passed by each applicant, and his name inscribed in the Register of Medical Students, previous to the commencement of his medical studies. Masters and Bachelors of Arts of any British or foreign university, whose course of study may from time to time be approved by the College, will be exempted from the Preliminary Examination; also those who have passed the examination of the national educational bodies, or of any recognised licensing board.

---

* Candidates can claim exemption from examination in Medicine under the following conditions—viz.: 1. The production by the candidate of a degree, diploma, or licence in Medicine entitling him to register under the Medical Act of 1858; or a degree, diploma, or licence in Medicine of a colonial or foreign university approved by the Council of the College. 2. A declaration by the candidate, prior to his admission to the Final Examination for Membership or Fellowship, that it is his intention to obtain either of the medical qualifications mentioned in the foregoing paragraph, in which case the diploma of the College will not be issued to him until he shall produce either the said medical qualification or proof of having passed the several examinations entitling him to receive the same.

The Professional Examination will be divided into two parts, according to the following arrangement of subjects:—1. Anatomy, Physiology, Chemistry. 2. Materia Medica and Pharmacy, Pathology and Pathological Anatomy, Practice of Medicine, Surgery, Midwifery, Medical Jurisprudence, Clinical Medicine. No candidate will be admitted to the first examination until the end of his second winter session, or to the second until he has completed four years of professional study. The examinations will be partly oral, partly in writing.

Candidates for the licence of the College who have passed the First Professional Examination before a qualifying body (provided it be as extensive as that required by this College) will be at once admitted to the second part of the examination.

Meetings for the examination of candidates who already possess a qualification from a recognised licensing body will be held on the first Wednesday of every month (except September and October), and, if necessary, on the following days. Candidates are required to communicate with the secretary to the College not less than eight days before the date of the examination at which they propose to appear.

No candidate is admissible to examination who has been rejected by any licensing board within three months previous to his examination.

The fee payable by a licentiate is £10 10*s*. In the event of a candidate being unsuccessful at his examination, the sum of £2 2*s*. will be retained to defray expenses.

Candidates may be admitted to special examination, on days other than those appointed above, on bringing forward reasons satisfactory to the Council, and on paying an extra fee of £5 5*s*. Should the candidate be unsuccessful, the sum of £8 8*s*. will be returned to him.

The Membership.—Any licentiate of a College of Physicians, or graduate of a British or Irish university, with whose knowledge of medical and general science the College may be satisfied, may be admitted a member of the College, provided he shall have attained the age of twenty-four years.

The Fellowship.—No one can be elected a Fellow of the College until he has been at least one year a member thereof, and has attained the age of twenty-five years.

The fee to be paid by a member is £31 10*s*. When a licentiate is raised to the rank of a member, he pays £21. When a member is raised to the rank of a fellow, the fee is £31 10*s*., exclusive of stamp duty, which amounts to £25. All candidates for fellowship or membership must lodge their fees, and the amount of stamp duty payable at the time to Government, with the treasurer, previously to presenting their petitions.

Qualification in Public Health.—The College now confers certificates of competency in Public Health. Examinations are held in April and October. Fee for certificate £10 10*s*.

ROYAL COLLEGE OF SURGEONS, EDINBURGH.

Every candidate for a surgical diploma must have followed his course of study in a university, or in an established school of medicine, or in a provincial school specially recognised by the College of Surgeons of that division of the United Kingdom in which it is situate.

Preliminary Examination.—All students who intend becoming candidates for the diploma of the College must have passed the complete examination in general education as prescribed by the General Medical Council (see *ante*), and have had their names inscribed in the Register of Medical Students at the commencement of their professional studies. Testimonials of proficiency granted by educational bodies recognised by the Medical Council exempt students from the Preliminary Examination.

Professional Education.—Candidates commencing professional study after Oct. 1st, 1866, must have been engaged, during four years after the examination in general education, in professional study, which shall include not less than four winter sessions', or three winter and two summer sessions' attendance at a recognised medical school.

Professional Examination.—Candidates are subjected to two Professional Examinations, conducted at separate sittings, partly in writing and partly orally.

The First Examination embraces Anatomy, Physiology, and Chemistry.

Candidates who desire to pass the First Professional Examination must apply to the Secretary on or before the Saturday preceding the day of examination, and must produce tickets and certificates of attendance in regard to all those courses of study which have reference to the subjects of that examination. They must also produce evidence of having passed the Preliminary Examination.

The sum of £4 must be paid to the treasurer of the College for this examination not later than 10 A.M. of the day preceding it. This sum will be considered as paid to account of the entire fee of £10 payable for the diploma.

In the case of a candidate being unsuccessful at this examination, £2 will be returned to him, the remaining £2 being retained to meet the expenses of the examination.

The Second Examination embraces Surgery and Surgical Anatomy; also Medicine, Midwifery, Materia Medica, and Medical Jurisprudence; and does not take place before the termination of the winter session of the last year of study. In the case of candidates who began their course of study after 16th October, 1866, it will not take place till four years after the examination in general education.

Application for examination must be made to the secretary not later than the Tuesday previous to the day of the First Examination.

Every candidate must produce to the secretary—1. Satisfactory evidence of his having attained the age of twenty-one years, and of having been duly registered. 2. The tickets and certificates of his classes. 3. The certificate of his having passed the First Professional Examination. And 4. A tabular statement (for which a printed form will be furnished by the officer) exhibiting the full amount of his professional education, and distinguishing the classes, hospitals, and dispensaries attended during each session of his studies. If he have been an apprentice, he must also insert the name of his master, the date of his indenture, and the length of time for which he was bound. This statement, accurately filled up, must be attested by his signature, and will be preserved by the College.

If the candidate have been an apprentice to a Fellow of the College, he must also produce his discharged indenture.

The remaining fee payable to the College (being £6), together with the receipt for the fee paid for the First Professional Examination, must be lodged not later than 10 A.M. of the day preceding the examination day in the hands of the treasurer, who will certify this upon the secretary's letter. £4 will be returned to unsuccessful candidates.

Candidates who have passed the First Examination in Anatomy, Physiology, and Chemistry, at any of the licensing boards recognised by the Medical Act, will be admissible to the Second Professional Examination on producing certificates of the whole course of study, of having passed their Preliminary and First Professional Examinations, and of having been registered. If any of the three subjects of the first examination have been omitted, such candidates will have to undergo an examination on the omitted subjects; and none of the subjects set down will be omitted at the second examination, even if some of them should have formed part of the first examination by another board. The fee will be £10. Unsuccessful candidates under this regulation will receive back £8.

In order to test more effectually the practical knowledge of candidates, recent dissections, anatomical specimens, and articles of the materia medica will be employed during the examinations; and all candidates will be required to write out formulæ of prescriptions. They will also be subjected to a practical clinical examination in the surgical hospital, including the application of surgical apparatus, bandages, &c.

No candidate shall be admissible to examination who has been rejected by any other licensing board within the three months preceding his application to be examined.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS, EDINBURGH.

The Royal College of Physicians of Edinburgh and the Royal College of Surgeons of Edinburgh, while they still continue to give their diplomas separately, under separate regulations, have made arrangements by which, after one series of examinations, the student may obtain the diplomas of both Colleges. The general principle of this joint examination is, that it shall be conducted by a board in which each body is represented in those branches which are common to both medicine and surgery; but that the College of Physicians shall take exclusive charge of the examination in Medicine and the College of Surgeons of the examination in Surgery. The object of the joint examination is to give to students facilities for obtaining from two separate bodies, and at less expense, a qualification in Medicine and a qualification in Surgery. Students passing that examination successfully will be enabled to register two qualifications under the Medical Act—Licentiate of the Royal College of Physicians of Edinburgh, and Licentiate of the Royal College of Surgeons of Edinburgh. The arrangement for thus conferring a double qualification by the co-operation of the two Colleges is in conformity with Section 19 of the Medical Act, and has received the special sanction of the General Council of Medical Education and Registration.

The regulations as to professional education, and the examinations for the double qualification, are almost identical with those prescribed for the single diploma of the Royal College of Surgeons of Edinburgh; the fees, however, differ to some extent.

Candidates may obtain all necessary information from Dr. Gairdner, Inspector and Treasurer of the Double Qualification, at 45, Northumberland-street, Edinburgh.

FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

Preliminary Examinations in General Literature, in accordance with the regulations of the General Council, will be held in the Faculty Hall during the session 1875–76 on the following days, commencing at 11 o'clock—namely, Friday, Oct. 8th, and Friday, Oct. 22nd, 1875; Friday, April 21st, 1876; Friday, July 21st, and Friday, 15th Sept., 1876; and on each occasion the examination will be continued on the succeeding day. Those who are unsuccessful may appear at one subsequent examination without paying a second fee. The fee for the examination and certificate is 10*s*., payable to the secretary previous to the examination.

The course of study for the diploma and the regulations generally correspond with those required by the Royal College of Surgeons of Edinburgh.

The examination is held on the second Tuesday of every month, August excepted, and extends over the subsequent day. Candidates will not be admitted to the final examination until the expiry of four years from the date of registration, which period must embrace at least three winter and two summer sessions, or four winter sessions, of study at a medical school.

The regulations regarding special examinations are nearly similar to those of the Royal College of Surgeons of Edinburgh.

The fee for the diploma is £10—£4 for the first and £6 for the second examination.

REGULATIONS REGARDING THE DOUBLE QUALIFICATION.

The Faculty of Physicians and Surgeons of Glasgow, and the Royal College of Physicians, Edinburgh, grant their diplomas conjointly before a board of examiners in which each body is represented, the object being to give to students facilities for obtaining from two separate bodies, and at less expense, a double qualification in Medicine and Surgery. Students passing this examination successfully will be enabled to register two qualifications under the Medical Act—namely, Licentiate of the Faculty of Physicians and Surgeons of Glasgow, and Licentiate of the Royal College of Physicians of Edinburgh. The curriculum of study embraces a course of Medicine, in addition to the subjects required for a diploma of the Faculty. The fee for the first examination is £6; for the second, £10.

The Examination for the Double Qualification will be held in the Faculty Hall, Glasgow, at the following periods—namely, First Examination, October 7th, 1875, January 12th, April 1st, May 4th and 6th, and July 27th, 1876. The Second Examination will take place, the written part on each of the above days, and the clinical and oral parts on the succeeding day.

Applications to be admitted to either the first or second examination must be made to the Secretary of the Faculty not later than the Monday preceding the examination.

The other regulations are nearly the same as those for the diploma of the Faculty.

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.

Candidates for the Licence in Medicine are required to give proof of having been engaged during a period of four years in the study of Medicine, and also to produce evidence of having studied, at a school or schools recognised by the College, the following subjects:—Anatomy, Physiology, Practical Anatomy, Chemistry, Practical Chemistry, Materia Medica and Botany, Medical Jurisprudence, Practice of Medicine and Pathology, Surgery, Midwifery; and of having attended a medico-chirurgical hospital in which regular courses of clinical lectures are delivered, together with clincal instruction, for twenty-seven months, or such hospital for eighteen months, with nine months' attendance on a medical hospital, and similar courses of clinical lectures and clinical instruction, the attendance in each case being for not more than nine months in any year, and the attendance on a medico-chirurgical hospital and medical hospital not being taken out in the same year; and of having attended Practical Midwifery for six months at a recognised lying-in hospital, or produce evidence satisfactory to the College, in each individual case, of having attended Practical Midwifery. Candidates must also produce certificates of character from two registered physicians or surgeons.

The examinations are held on the second Tuesday and two following days in each month, except August and September.

Gentlemen holding a Medical or Surgical qualification, who may desire to obtain the licence in Midwifery, will be required to undergo a special examination.

The fee for the Licence is £15 15*s*. Fee for the Midwifery diploma, £3 3*s*.; for the licences in Medicine and Midwifery, if taken out within an interval of a month, £16.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

Letters Testimonial.—Every person requiring to be registered as a pupil on the College books must first pay a registry fee of five guineas. Registered pupils are admitted to the Preliminary Examination at any period previous to the examination for Letters Testimonial. Students who are not registered pupils are also admitted to the Preliminary Examination upon payment of a matriculation fee of ten shillings; but they are not enrolled as registered pupils, or entitled to the privileges reserved for such pupils, until they have paid the full registration fee of five guineas.

Examinations are held quarterly, on the second Tuesday in January, April, July, and December, at which candidates are divided into two classes—junior and senior.

The junior class must produce certificates of having attended three courses of lectures on Anatomy and Physiology, three courses of lectures on Practical Anatomy, with dissections; two courses of lectures on Chemistry, one course of lectures on Materia Medica, one course of lectures on Botany, and one course of lectures on Forensic Medicine. This class is examined in Anatomy, Physiology, and Materia Medica.

The senior class must produce certificates of having attended three courses of lectures on the Theory and Practice of Surgery, one course of lectures on the Practice of Medicine, and one course of lectures on Midwifery; also of attendance on a recognised hospital for three winter and three summer sessions. This class is examined in Surgery, Operative Surgery, Practice of Medicine, and forms of Prescription.

The fees are: 10*s*. for Preliminary Examination; £5 5*s*. as registered pupil of the College; £5 5*s*. for the Junior Class Examination, which is not returned in case of rejection, but is allowed in the fee for his second examination; £15 15*s*. for the Senior Class Examination—total £26 15*s*. In addition to the foregoing, a fee of £1 1*s*. is to be paid to the registrar on handing each licentiate his diploma.

Every candidate rejected at the quarterly examination is required to pay to the College the sum of £2 2*s*. on applying for re-examination.

Fellowship.—A registered pupil or licentiate is admitted to examination for the Fellowship if he shall have laid before the Council the following documents:—A receipt showing that he has lodged in the Bank of Ireland, for the use of the College, if he be a licentiate, the sum of twenty guineas, or thirty-five in case he be a registered pupil, provided in either case he intends to reside beyond ten miles from Dublin. Should the candidate intend to reside in Dublin, or within ten miles thereof, he shall lodge, if he be a licentiate, thirty guineas; or, if he be a registered pupil, forty-five guineas. Fellows entering on the country list, who may subsequently settle as practitioners in Dublin, or within ten miles thereof, shall pay ten guineas to the College. Certificates that he is twenty-five years of age; that he is a Bachelor of Arts of some university, or that he has been examined in such a manner as the Council may from time to time direct, with a view to ascertain that he has obtained a liberal preliminary education; of good general conduct during his professional education; that he has been engaged in the acquisition of professional knowledge for a period of not less than six years, during three of which he must have studied in one or more of the schools and hospitals recognised by the Council. He may have studied for the other three years in any school or schools of the United Kingdom which shall be approved by the Council, or in any foreign school of repute. It is also required that the candidate shall have had opportunities of practical instruction as house-surgeon or dressers in a recognised hospital. Certificates of attendance on the several courses of lectures required to be attended by candidates for Letters Testimonial, together with one course of lectures on Comparative Anatomy, and one course of lectures on Natural Philosophy. A thesis on some medical subject or clinical reports, with observations of six or more medical or surgical cases taken by himself.

Midwifery.—Any Fellow or Licentiate of the College may be admitted to an examination for the diploma in Midwifery upon laying before the Council the following documents:—A certificate showing that he has attended one course of lectures on Midwifery and Diseases of Women and Children, delivered by a professor or lecturer in some school of medicine or surgery recognised by the Council. A certificate showing that he has attended the practice of a lying-in hospital, recognised by the Council, for a period of six months, or the practice of a dispensary for lying-in women and children recognised by the Council, and devoted to this branch of surgery alone. A certificate showing that he has conducted thirty labour cases at least.

Candidates for the Midwifery diploma are publicly examined on the Organisation of the Female, the Growth and Peculiarities of the Fœtus, the Practice of Midwifery, and the Diseases of Women and Children; and, if approved of, shall receive a licence or diploma certifying the same.

The candidate pays £1 6*s.* for the Midwifery diploma, provided he takes it out within one month from the date of his Letters Testimonial; after that date, £2 2*s.*

THE SOCIETY OF APOTHECARIES, LONDON.

Every candidate for a Certificate of Qualification to practise as an Apothecary will be required to produce testimonials—Of having passed a Preliminary Examination in Arts, as a test of general education. Of having attained the full age of twenty-one years. Of good moral conduct. Of having had three months' Practical Pharmacy from some recognised hospital or dispensary, or from a qualified practitioner; the apprenticeship not being required. And of having pursued a course of medical study in conformity with the regulations of the Court. Of having served the office of clinical clerk at a recognised hospital during the period of six weeks at least; and also that they have been examined at the class examinations instituted by the various lecturers and professors of their respective medical schools and colleges.

Course of Study.—Every candidate must attend the following lectures and medical practice during not less than three winter and two summer sessions; each winter session to consist of not less than six months, and to commence not sooner than the 1st nor later than the 15th of October; and each summer session to extend from the 1st of May to the 31st of July.

First Year.—Winter Session: Chemistry, Anatomy and Physiology, Dissections. Summer Session: Botany, Materia Medica and Therapeutics, Practical Chemistry.[*]

Second Year.—Winter Session: Anatomy and Physiology, including Dissections and Demonstrations; Principles and Practice of Medicine; Clinical Medical Practice. Summer Session: Midwifery and Diseases of Women and Children, and Vaccination;[†] Forensic Medicine and Toxicology; Clinical Medical Practice.

Third Year.—Winter Session: Principles and Practice of Medicine, Clinical Medical Lectures, Morbid Anatomy, Clinical Medical Practice.

No certificates of lectures or of anatomical instructions delivered in private to particular students, apart from the ordinary classes of recognised public medical schools, can be received by the Court of Examiners.

All students are required personally to register the several tickets of admission to lectures and medical practice within the first fifteen days of the months of October and May.

Examination in Arts.—An Examination in Arts will take place at the Hall three times in the year—viz., on the last Friday and Saturday in the months of January, April, and September.[‡] Candidates applying to be admitted to any examination must pay the fee (one guinea) at least one week before the examination, and must sign their names in the candidates' book before 10 A.M. and 4 P.M. o'clock not later than the previous Thursday. If a candidate fail to pass the examination, the fee will not be returned to him, but he will be admissible to either or both of the two next following examinations in Arts without the payment of an additional fee, upon giving at least one week's notice, and signing the candidates' book. Testimonials of Proficiency in General Education will be received as exempting from the Examination in Arts at the Hall from the national, colonial, and foreign educational bodies recognised by the General Council, and also from any of the recognised licensing bodies.

Professional Examinations.—The Court of Examiners meet in the Hall every Wednesday and Thursday, where candidates are required to attend at 4.30 P.M. Every person intending to offer himself for examination must give notice in writing to the Clerk of the Society on or before the Monday previous to the day of examination, and must at the same time deposit all the required testimonials (as before specified), with the fee, at the office of the Beadle, where attendance is given every day except Sunday, from 10 to 4 o'clock, and Saturdays from 10 to 2. The examination of candidates is divided into two parts, and is conducted partly in writing and partly *vivâ voce.*

The written examination will take place on Wednesdays, and the *vivâ voce* examination on Thursdays.

First Examination, which may be passed after the second winter session, embraces the following subjects:—The Latin of Physicians' Prescriptions and Pharmacy, Anatomy and Physiology, General and Practical Chemistry, Botany and Materia Medica.

Second or Pass Examination, after the third winter session (the four years' course of study being completed):—Principles and Practice of Medicine, Pathology, Therapeutics, Midwifery, including the Diseases of Women and Children; Forensic Medicine and Toxicology.

1. All graduates in Medicine of British universities will be admitted to a clinical and practical examination in the Practice of Medicine and Midwifery.

2. Licentiates of the Royal College of Physicians, London; of the Royal College of Physicians, Edinburgh; of

---

[*] By Practical Chemistry is intended a specific course of instruction in the Laboratory, with an opportunity of personal manipulation in the ordinary processes of Chemistry, and of acquiring a knowledge of the various reagents for poisons.

[†] A certificate of attendance on not less than twenty cases will be received from a legally qualified practitioner.

[‡] The following is the syllabus of subjects for examination in 1876:—1. *The English Language:* The leading features of its History; its Structure and Grammar. English Composition. 2. *The Latin Language:* January Examination—Virgil; Æneid, Book IV. April Examination—Horace; Odes, Book I. September Examination—Cicero; De Senectute. Retranslation of easy sentences. Grammatical Questions will be introduced into the Latin Paper, and each candidate will be expected to give satisfactory answers to these. 3. *Mathematics:* The Ordinary Rules of Arithmetic. Vulgar and Decimal Fractions. Addition, Substraction, Multiplication, and Division of Algebraical Quantities. Simple Equations. The First Two Books of Euclid. 4. (*a*) *Greek:* Xenophon; Anabasis, Books I. and II. Grammatical Questions. (*b*) *French:* Molière; L'Avare. Translation from English into French. Grammatical Questions. (*c*) *German:* Fouqué; Undine. Translation from English into German. Grammatical Questions. (*d*) *Natural Philosophy:* Mechanics. Hydrostatics and Pneumatics. [The books recommended for study in this subject are Smith's "Statics," and Smith's "Hydrostatics," or Newth's "Natural Philosophy."]

the Royal Colleges of Physicians and Surgeons, Edinburgh; of the King and Queen's College of Physicians, Ireland; of the Faculty of Physicians and Surgeons, Glasgow; and of the Apothecaries' Hall, Dublin, will be admitted to a clinical and practical examination in the Practice of Medicine, Midwifery, Forensic Medicine, and Toxicology.

3. Any candidate who has passed his first examination for the licence of the King and Queen's College of Physicians, Ireland; the joint licence of the Royal Colleges of Physicians and Surgeons, Edinburgh; or for the single licence of the College of Physicians, Edinburgh; the licence of the Faculty of Physicians and Surgeons, Glasgow; the first Professional Examination for the degree of M.B., or Master in Surgery in the Universities of Oxford, Cambridge, or London; or the second part of the Professional Examination for the degree of M.B. or Master in Surgery in the Universities of Edinburgh, Aberdeen, St. Andrews, and Glasgow; or the first Examination for medical and surgical degrees in the Irish universities; or the first Examination for the licence of the Apothecaries' Company, Dublin, will be admitted to a single examination in Anatomy and Materia Medica (*to those candidates who have not undergone an examination in those subjects*), Practice of Medicine, Pathology, Therapeutics, Midwifery, Forensic Medicine, and Toxicology, which examination will be partly written and partly *vivâ voce*.

4. Members of the Royal College of Surgeons, England; Licentiates of the Royal College of Surgeons, Edinburgh; and Licentiates of the Royal College of Surgeons, Ireland; and all candidates who have passed the First Anatomical Examination of the Royal College of Surgeons, London; the Royal College of Surgeons, Edinburgh; and the Royal College of Surgeons, Ireland, are exempt from *writing* on Anatomy and Physiology *only* in their first examination.

5. Members of the Royal College of Surgeons, England; Licentiates of the Royal College of Surgeons, Edinburgh; and Licentiates of the Royal College of Surgeons, Ireland; and all candidates who have passed the First Anatomical Examination of the Royal College of Surgeons, London; the Royal College of Surgeons, Edinburgh; the Royal College of Surgeons, Ireland, are exempt from *writing* on Anatomy and Physiology *only* in their first examination.

All candidates, unless registered, will be required to produce their diploma.

The examination of candidates for certificates of qualification to act as Assistant, in compounding and dispensing medicines, will be as follows:—In translating Physicians' Prescriptions; in the British Pharmacopœia; in Pharmacy, Pharmaceutical Chemistry, Materia Medica, and Botany.

Any candidate who presents himself for the first examination, and is rejected, may be admitted to re-examination at the expiration of three months. A candidate who presents himself for the second or Pass Examination, and is rejected, cannot be admitted to re-examination until the expiration of six months. No rejected candidate can be re-examined as an Assistant until the expiration of three months.

Fees.—For a Certificate of Qualification to practise, six guineas, half of which is retained in case of rejection, to be accounted for at a subsequent examination. For the First Examination, three guineas. For an Assistant's Certificate, two guineas. Both of these sums are retained in case of rejection, and accounted for subsequently.

Students' Prizes.—The Society of Apothecaries annually offer two prizes for proficiency in the knowledge of Botany, and also two prizes for proficiency in the knowledge of Materia Medica and Pharmaceutical Chemistry. The prizes consist of a Gold Medal, awarded to the candidate who distinguishes himself the most in the examination; and of a Silver Medal and a Book to the candidate who does so in the next degree. Regulations of competitors for the prizes can be had on application.

The Society's Botanic Garden at Chelsea is open daily (except Sunday) from 10 till 5 P.M. Tickets of admission may be had at the Beadle's Office, Apothecaries' Hall, Blackfriars, E.C.

APOTHECARIES' HALL OF IRELAND.

A Preliminary Examination will be held at the Hall four times in the year—namely, on the third Thursday in the months of January, April, July, and October, at 12 o'clock. Subjects: English, Mathematics, French or German, Latin, Greek, Natural Philosophy, Natural History.

Professional Education and Examination.—Every candidate for the licence to practise must produce certificates to the following effect:—1. Of having passed an examination in Arts, previously to entering on professional study. 2. Of being registered as a student in Medicine. 3. Of being at least twenty-one years of age, and of good moral character. 4. Of apprenticeship to a qualified apothecary, or of having been engaged in Practical Pharmacy with an apothecary for three years subsequently to having passed the examination in Arts. 5. Of having spent four years in professional study. 6. Of having attended the following courses—namely: Chemistry, during one winter session; Anatomy and Physiology, during two winter sessions; Demonstrations and Dissections, during two winter sessions; Botany and Natural History, during one summer session; Practical Pharmacy and Practical Chemistry (in a recognised laboratory), each during three months; Principles and Practice of Medicine, and Therapeutics, during one winter session; Midwifery and Diseases of Women and Children, during six months; Practical Midwifery at a recognised hospital (attendance upon twenty cases); Surgery, during one winter session; Medical Jurisprudence, during one summer session; instruction in the practice of Vaccination. 7. Of having attended at a recognised hospital or hospitals the Practice of Medicine and Clinical Lectures on Medicine during two winter and two summer sessions; also the Practice of Surgery and Clinical Lectures on Surgery during one winter and one summer session.

The *Professional Examinations* will be held quarterly, and will commence on the first Monday in the months of January, April, July, and October. They will be divided into two parts: the first comprehending Chemistry, Botany, Anatomy, Physiology, and Pharmacy; the second, Medicine, Therapeutics, Surgery, Pathology, Midwifery, Forensic Medicine, and Hygiene.

Candidates for the licence must lodge their testimonials, and enrol their names and addresses, with the clerk at the Hall, in Dublin, a week prior to the day of examination.

Candidates who fail to pass the first part of the Professional Examination will be remitted to their studies for three months, and unsuccessful candidates at the Pass Examination will not be readmitted until after the expiration of six months.

Doctors of Medicine of any of the universities of the United Kingdom, and Licentiates of a Royal College of Physicians, or Surgeons of any of the Royal Colleges of Surgeons, whose qualifications as such appear in the Medical Register, and who, having first passed an examination in Arts, have also served an apprenticeship, or the required term at Practical Pharmacy, to a qualified apothecary, may obtain the licence of the Hall by undergoing an examination—the former in Pharmacy, and the latter in Medicine and Pharmacy. Licentiates of the Society of Apothecaries of London are admitted *ad eundum*.

An Honour Examination for Apprentices is held at the Hall in the first week of May annually, upon some subject of Medical or Pharmaceutical Chemistry, which is announced by the Council of the Hall at the commencement of the previous winter session, and a prize of five guineas is awarded to the successful competitor.

ARMY MEDICAL DEPARTMENT,

6, Whitehall-yard, S.W.

Every candidate desirous of presenting himself for admission to the Army Medical Service must be unmarried, and not under twenty-one nor over twenty-eight years of age. He must produce certificates of date of birth and of moral character.

The candidate must make a declaration that both his parents are of unmixed European blood, and he labours under no mental or constitutional disease, nor any imperfection or disability that can interfere with the most efficient discharge of the duties of a medical officer in any climate. His physical fitness will be determined by a Board of Medical Officers, who are required to certify that the candidate's vision is sufficiently good to enable him to perform any surgical operation without the aid of glasses. The Board must also certify that he is free from organic or other disease, and from constitutional disability likely to unfit him for military service in any country.

The candidate must possess two diplomas or licences, one to practise Medicine and the other Surgery in Great Britain or Ireland, and must be registered under the Medical Act in force at the time of his appointment.

Certificates of registration, character, and age must accompany the form of application.

After complying with the foregoing regulations, candidates will be examined by the Examining Board in the following compulsory subjects:—Anatomy and Physiology; Surgery; Medicine (including Therapeutics and the Diseases of Women and Children); Chemistry and Pharmacy, and a practical knowledge of drugs. The examination in Medicine and Surgery will be in part practical, and will include operations on the dead body, the application of surgical apparatus, and the examination of medical and surgical patients at the bedside.

The eligibility of each candidate for the Army Medical Service will be determined by the result of the examinations in these subjects only.

Examinations will also be held in the following voluntary subjects—French, German, and Natural Sciences.

The knowledge of modern languages being considered of great importance, all intending competitors are urged to qualify in French and German.

The Natural Sciences will include Comparative Anatomy, Zoology, Natural Philosophy, Physical Geography, and Botany with special reference to Materia Medica.

The number of marks gained in both the voluntary subjects will be added to the total number of marks obtained by those who shall have been found qualified for admission, and whose position on the list of successful competitors will thus be improved in proportion to their knowledge of modern languages and natural sciences.

After passing this examination, every candidate will be required to attend one entire course of practical instruction at the Army Medical School on—Hygiene, Clinical and Military Medicine, Clinical and Military Surgery, Pathology of Diseases and Injuries incident to Military Service. At its conclusion the candidate will be required to pass an examination on the subjects taught in the school. If he gives satisfactory evidence of being qualified for the practical duties of an army medical officer, he will be eligible for a commission as surgeon.

During the period of his residence at the Army Medical School each candidate will receive an allowance of 5*s.* per diem with quarters, or 7*s.* per diem without quarters, to cover all cost of maintenance; and he will be required to provide himself with uniform (viz., the regulation undress uniform of a surgeon, but without the sword).

ARMY MEDICAL SCHOOL.

Royal Victoria Hospital, Netley.

All gentlemen who have been successful in the competitive examinations, held twice a year (February and August), in London, for appointments in the medical services of the Army (British and Indian) and of the Navy, attend subsequently, at the Royal Victoria Hospital, a course of practical instruction in the duties they will have to perform in the public services. The course lasts four months; at the end of the session an examination is held to ascertain the progress made by the candidates, who are afterwards gazetted as surgeons, taking their seniority according to the aggregate number of marks then gained at both the London and the Netley examinations. The lectures on Military Surgery include gunshot and other wounds; arrangement for the transport of wounded; duties of army surgeons in the field, during sieges, on transports, &c.; and other special subjects. Those on Military Medicine refer to the tropical and other diseases of the British possessions and colonies, and to the losses by disease in peace and war, at home and abroad. The lectures on Hygiene comprise the examination of water and air, of food, clothing, &c., of the soldier, his duties and exercise, and the circumstances affecting his health; the subjects of meteorology, statistics, and the prevention of the different diseases met with in the army, on home or foreign service. The lectures on Pathology have reference chiefly to Morbid Anatomy and the scientific examination of tropical diseases, and of other complaints which the army surgeon is especially called on to investigate. The candidates also attend the wards of the hospital to study the diseases of invalids under the Professors of Medicine and Surgery, the system of recruiting, and the modes of keeping the army medical returns and records. They are also called on to make post-mortem examinations, to operate on the dead body, and pass through courses of practical instruction in the laboratory on the modes of recognising the qualities and adulterations of food, and in the microscope-room on the modes of microscopic examination of morbid tissues and of adulterations of food, &c. Visits are also paid at stated intervals to the lunatic hospital attached to the Royal Victoria Hospital, and instruction is given by the surgeon-major in charge.

INDIAN MEDICAL SERVICE.

India Office, St. James's-park, S.W.

All natural-born subjects of her Majesty, between twenty-two and twenty-eight years of age at the date of examination, and of sound bodily health, may be candidates for the appointment of Surgeon in her Majesty's Indian Medical Service. They may be married or unmarried.

They must subscribe and send in to the Military Secretary, India Office, Westminster, proofs of their qualification similar to those required by the Army Medical Department.

Degrees, diplomas, licences, and certificates of their registration in accordance with the Medical Act of 1858, must be lodged at the India Office, for examination and registry, at least one fortnight before the candidate appears for examination. The regulations, subjects, and times for examination are the same as for the Army Medical Department. Passage allowance to India on appointment will be given, or a passage provided. When passages are provided on board the Indian troop-ships, a charge for messing will be made at the rate laid down in the Royal Passage Warrant of 1865. Pay at 10*s.* a day will be allowed from date of passing Final Examination at the Army Medical School.

Indian allowances and time of service for pension will reckon from the date of arrival in India. The period of residence at the Army Medical School will reckon as service for the full-pay pension only.

Surgical instruments are provided in India by the Government for the use of medical officers.

NAVAL MEDICAL SERVICE.

Admiralty, 9, New-street, Spring-gardens, S.W.

Every candidate desirous of presenting himself for admission to the Naval Medical Service must not be under twenty-one nor over twenty-eight years of age. He must produce a certificate from the district registrar, in which the date of birth is stated; or, if this cannot be obtained, an affidavit from one of the parents or other near relative, who can attest the date of birth, will be accepted. He must also produce a certificate of moral character. The candidate must make a declaration that he labours under no mental or constitutional disease, nor any imperfection or disability that can interfere with the most efficient discharge of the duties of a medical officer in any climate. He must also attest his readiness to engage for general service, and to proceed on foreign service when required to do so. The candidate must be registered under the Medical Act in force at the time of his appointment as licensed to practise medicine and surgery in Great Britain or Ireland.

Candidates will be examined by the Examining Board in the following subjects:—Anatomy and Physiology; Surgery; Medicine (including Therapeutics and the Diseases of Women and Children); Chemistry and Pharmacy, and a practical knowledge of drugs. (The examination in Medicine and Surgery will be in part practical, and will include operations on the dead body, the application of surgical apparatus, and the examination of medical and surgical patients at the bedside). The eligibility of each candidate for the Naval Medical Service will be determined by the result of the examinations in these subjects only.

Candidates who desire it will be examined in Comparative Anatomy, Zoology, Natural Philosophy, Physical Geography, and Botany with special reference to Materia Medica, also in French and German, and the number of marks gained in these subjects will be added to the total number of marks obtained in the obligatory part of the examination by candidates who shall have been found qualified for admission, and whose position on the list of successful competitors will thus be improved in proportion to their knowledge of these branches of science.

METROPOLITAN HOSPITALS AND MEDICAL SCHOOLS.

St. Bartholomew's Hospital and College. — The clinical practice of the hospital comprises a service of 710 beds, of which 676 are in the hospital at Smithfield, and 34 are for convalescent patients at Lauderdale House, Highgate.

Pupils' Appointments.—Four house-physicians and four house-surgeons are appointed annually, each of them holding office for one year, and provided with rooms by the hospital authorities. The fee payable for the house-physicianships and house-surgeoncies is only nominal. The midwifery assistant is appointed for a year, and is provided with rooms by the hospital authorities. The ophthalmic house-surgeon is appointed for six months, and is eligible for re-election for a second term of six months. The assistant chloroformist is appointed annually, and receives rooms and a salary of £25. No fee is paid for any of these appointments.

The clinical clerks, the obstetric clerks, the clerks to the medical out-patients, the dressers to the surgical out-patients, and the dressers in the special departments are chosen from the diligent students. No fee is required for any of these appointments. Sixteen ward dresserships are given annually to the students (of the second year) who pass the best examination in the subjects of study of the first and second year, or who may be otherwise especially recommended for such appointments. Other ward-dresserships may be obtained by payment of the usual fees.

A College is attached to the hospital, in which students can reside, subject to the College regulations. By applying to the warden, students will obtain information respecting rooms in College, or will be advised respecting residence out of the hospital.

Foundation and other Prizes.—Open Scholarship in Science (founded 1873). This Scholarship, of the value of £100, tenable for one year, will be competed for September 25th. Candidates must not be more than twenty-five years of age, and must not have entered to the medical or surgical practice of any metropolitan medical school. The subjects of examination are Physics, Chemistry, Botany, and Zoology.—Preliminary Scientific Exhibition (founded 1873). The subjects of examination are identical with those of the Open Scholarship in Science. This Exhibition, of the value of £50, is tenable for one year. The examination is confined to students of the hospital of less than six months' standing, and will be held October 27th.—The Jeaffreson Exhibition, of the value of £20 yearly, and tenable for two years, is awarded, in October, to the student who passes the best examination in the subjects of General Education.—A Senior Scholarship, £50, in Anatomy, Physiology, and Chemistry.—Lawrence Scholarship, and Gold Medal, of the value of forty-five guineas (founded in 1873 by the family of the late Sir Wm. Lawrence).—Two Brackenbury Scholarships in Medicine and Surgery.—Junior Scholarships in the subjects of study of the first year: 1. £50; 2. £30; 3. £20.—The Wix Prize is awarded for the best essay on a given subject.—The Bentley Prize for the best report on Surgical cases occurring in the wards of the hospital during the previous year. The Kirkes Gold Medal for Clinical Medicine.—The Hichens Prize for the best examination in "Butler's Analogy."—Foster Prize for the best examination in Practical Anatomy (senior).—The Treasurer's Prize for the best examination in Practical Anatomy (junior).

Students preparing for their examinations are arranged in classes, and examined by the lecturers, demonstrators, and medical tutor.

An examination of all students of the first year is held at the close of the first winter and first summer sessions.

A class in the subjects required for Matriculation at the University of London is held from October to January, and from March to June. A class for the Preliminary Scientific Examination is held from January to July. Classes are also held for the first and second M.B. Examinations and in Logic for the M.D. Examination.

Courses of Practical Surgery and of Practical Physiology have been instituted in accordance with recent regulations of the Royal College of Surgeons.

The Anatomical Museum and the Museums of Materia Medica and of Botany are open daily from 10 till 4 o'clock.

Charing-cross Hospital and College.—The fee for matriculation is £2 2s., to be paid on entering. Matriculated students pay proportionately lower fees, and are admitted without additional fee to the special courses in Practical Surgery, the lectures on Psychological Medicine by Dr. Hunt, to the Physiological Laboratory for practical instruction in Histology, and to the practice of the Royal Westminster Ophthalmic Hospital. They alone are entitled to compete for the scholarships, medals, and prizes.

Two Entrance Scholarships, of the value of £30 and £20 respectively, tenable for one year, will be awarded annually in October, after a competitive examination in the following subjects:—*Compulsory,* English, Latin, French, *or* German, Mathematics; *Optional* (only one of which may be selected), Chemistry, Mechanics, German *or* French.

Two scholarships are open for competition among the matriculated students: the Llewellyn Scholarship of £25, for students who have just completed their second year; and the Golding Scholarship of £15, for students who have just completed their first year. The following medals are awarded annually: the Governors' Clinical gold medal; and silver and bronze medals in all classes.

St. George's Hospital.—Perpetual pupils, by payment of £105, are entitled to admission to the medical and surgical practice; to compete for prizes and exhibitions; to hold the appointments of house-physician and house-surgeon, assistant house-physician, assistant house-surgeon, ophthalmic assistant, and to become clinical clerks for two periods of three months each, and dressers for similar periods. The house-physician and house-surgeon now receive their board and lodging free, and *no payment* is made for the appointment. Clinical clerks and dressers are also appointed without payment. Gentlemen are admitted to the hospital practice and lectures required by the Colleges of Physicians and Surgeons and the Society of Apothecaries on payment of forty guineas at the commencement of the first winter session, forty guineas at the commencement of the second year of study, and ten guineas for each succeeding year, which entitles the pupil to hold the offices of clinical clerk and dresser for three months each, and to become a candidate for the offices of medical and surgical registrar and demonstrator of anatomy and curator of the museum. These are all salaried offices. The obstetric assistant is resident, with a salary of £100. He must be a legally qualified practitioner.

Pupils may enter to the hospital practice and lectures separately. The appointments of house-physician and house-surgeon are made every six months, are four in number, and are tenable for one year. These appointments are awarded after examination, and are given without fee or payment, each officer being lodged and boarded at the expense of the governors of the hospital. The whole of the patients are under the charge of these officers in the absence of the physicians and surgeons.

Prizes.—The William Brown Exhibition of £100 per annum, tenable for two years; open to any pupil of St. George's who is under twenty-five years of age, and who shall have obtained a diploma or licence entitling him to be registered as a practitioner of medicine or surgery in England, within two years previous to the period fixed for the examination (July). The examination is to test the proficiency of the candidate in Medicine, Midwifery, and Surgery, including Ophthalmic Surgery. The William Brown Exhibition of £40 per annum, tenable for three years, for general fitness for the exercise of the medical profession, and for moral conduct. Sir Charles Clarke's Prize (interest of £200 Consols) for good conduct. The Thompson Medal and the Treasurer's Clinical Prize for proficiency in the clinical examination of medical and surgical cases in the wards of the hospital, with observations on pathology and treatment. Sir Benjamin Brodie's Clinical Prize in Surgery, for the best report of Surgical cases which have occurred in the hospital during the preceding twelve months, with notes illustrative of their pathology, diagnosis, and treatment. The Acland Clinical Prize in Medicine for the best report of Medical cases which have occurred in the hospital during the preceding twelve months, accompanied by drawings, diagrams, and observations. The Henry Charles Johnson Memorial Prize, awarded at the end of the winter session to the pupil most distinguished in Practical Anatomy. The

Brackenbury Prize in Medicine, value nearly £40; the Brackenbury Prize in Surgery, value nearly £40; open to all pupils of the hospital who on April 30th have not completed the fourth year of study, although they may at the next ensuing examination (in May) possess a diploma entitling them to practise medicine or surgery.

At the close of the summer session an examination of all the pupils is held, and certificates of proficiency given to every one who passes to the satisfaction of the examiners. Three prizes of ten guineas each are awarded to the most distinguished student in the first, second, and third years of study respectively. All students who have passed the examinations in Anatomy and Physiology will be formed into classes under the personal supervision of the physicians and surgeons in the hospital, for instruction in diagnosis and the practice of medicine and surgery. In the selection of the house-physicians and house-surgeons, regard will be had to their work in the wards of the hospital, and to the examinations for the Clinical and General Proficiency Prizes.

GUY'S HOSPITAL.—House-physicians and house-surgeons, obstetric residents, dressers, clinical and other clerks, are selected from the students according to merit, and without payment. The house-physicians hold office for a period of six months each — three months as junior, and three as senior. The main duty of the junior house-physician is to attend the medical out-patients three times a week, in a room adjoining that occupied by the assistant-physician for the day, and to prescribe for those patients who are not seen by him. The senior house-physician is chiefly occupied in the wards, which he visits twice a day. He assists the permanent medical officer in attending to all the emergencies that may arise in the absence of the physician. The evening clinical observations of temperature, &c., are chiefly made by him. He has separate rooms in the clinical building, and is boarded at the charge of the hospital. The house-surgeons hold office for a period of four months, acting as junior for the first two months, and as senior for the last two months. The junior house-surgeon is provided with commons. He has the general superintendence of the surgical casualty department, and assists his senior when required. The senior house-surgeon resides in the hospital, and is boarded free of expense. In the absence of the surgeons and assistant-surgeons he has the general superintendence of the surgical wards. The dressers are selected from those gentlemen who have completed their third winter session, and who have been surgical ward clerks. They hold office for six months each. Three are attached to each surgeon. During their week of special duty they reside in the hospital, and board with the house-surgeons free of expense. The obstetric residents, two in number, reside and are boarded in the hospital. Each holds office for two months—one month as junior, and one month as senior. Their duties are to accompany the pupils to their first cases of labour, to assist them in difficult cases, and to superintend generally the working of the lying-in charity. They are not allowed to use instruments without the sanction of one of the obstetric physicians.

Prizes, &c.—Voluntary competitive examinations are held at four periods of the student's course. 1. The Entrance Examination (commencing this year on October 7th) comprises Classics and Mathematics, Modern Languages, Botany, Physics, and Chemistry. The candidate who distinguishes himself the most receives £60; the second candidate £30. 2. At the end of the first sessional year, in Anatomy, Physiology, Materia Medica, Chemistry, Botany, and Comparative Anatomy: first prize, £50; second, £25; third, £10 10*s.* (presented by one of the Governors). 3. At the end of the second sessional year, in Anatomy, Physiology, and Practical Physiology: first prize, £25; second, £10; 4. At the end of the third sessional year, in Medicine, Surgery, Midwifery, and Medical Jurisprudence: first prize, £35; second prize, £20. Honorary certificates are given to those candidates who pass creditable examinations. Two Gold Medals are given annually by the Treasurer to the students who, having completed their third and not exceeded their fourth year, most distinguish themselves at special examinations in Clinical Medicine and Clinical Surgery. One medal is awarded in each subject. The Physical Society awards the following prizes:—One of £5 to the member who sends in the best essay and report of cases; prizes of £10 and £5 for the best papers read before the Society; and one of £5 to the member who has most distinguished himself in the debates of the session.

The Library is supplied with weekly, monthly, and quarterly journals of medicine, natural history, and philosophy; it is open to the students daily from 10 A.M. to 4 P.M.

KING'S COLLEGE.—The physicians' assistants, the physician-accoucheur's assistant, the clinical clerks, and the house-surgeon and dressers, are selected by examination from among those matriculated students of the College who are pupils of the hospital. The College and Hospital fees, in the case of matriculated students, for the three years' course of study required by the regulations of the College of Physicians, the College of Surgeons, and the Society of Apothecaries, amount to £105. Payments for this course may be made by one sum of £100 on entrance, or by the following instalments: £52 10*s.* on entrance, £42 at the beginning of the second winter session, and £10 10*s.* at the beginning of the third winter session. If the course be extended over a longer period than three years, a further sum of £10 10*s.* will be required at the beginning of each subsequent winter session. Students are recommended to add to the above the fee for attendance on the Medical Tutor's class for one year—namely, £3 3*s.* for the first-year subjects, or in the case of those preparing for the Preliminary Scientific Examination of the University of London, £5 5*s.* All resident students are required to attend the tutor during their first year. Rooms are provided within the walls of the College for the residence of a limited number of matriculated students. Registration fee at hospital, 10*s.* 6*d.*

Scholarships.—Warneford Scholarships: Two of £25 per annum, for three years. Science: One of £30, for two years. College Scholarships: One of £40 per annum, for two years; one of £30, for one year; three of £20, for one year. The Daniell Scholarship, of the annual value of £20. Sambrooke Registrarships, of the annual value of £50 each, and tenable for two years, are open to all matriculated students who have filled any one of the higher appointments at the hospital, or who have become Associates. The Leathes Prizes, value £7, and the Warneford Prizes, value £40, are given annually amongst the matriculated medical students. Class prizes are awarded annually for proficiency in the several subjects of Anatomy, Physiology, Chemistry, Materia Medica, Surgery, Medicine, Obstetric Medicine, Botany, Forensic Medicine, Comparative Anatomy, Pathological Anatomy, Practical Physiology, and Practical Chemistry. These consist of books of the value of £3 in each subject of examination. Certificates of honour are also given. Two Medical Clinical Prizes, one of £3 for the winter session, and one of £2 for the summer session; and two Surgical Clinical Prizes, of the same value, are given. The Todd Medical Clinical Prize consists of a bronze medal and books to the value of £4 4*s.* The Tanner Prize for Obstetric Medicine, value £10, is given annually in July. All students, occasional as well as matriculated, are admitted to contend for the class prizes.

LONDON HOSPITAL.—At the Medical College lectures will be given on all the subjects required by the examining boards. For instruction in Mental Diseases, students can attend, without further fee, the practice of Dr. John Millar, medical superintendent of Bethnal House Asylum, a few minutes' walk from the hospital. Clinical lectures, both medical and surgical, will be given every week, and practical instruction imparted in all the departments.

Prizes.—Seven Scholarships to be offered for competition in the winter and summer sessions:—Two Entrance Science Scholarships awarded at the end of September of the value of £60 and £40 respectively. Two Scholarships of £30 and £20, to the students who pass in October the best and second-best examinations in the subjects required at the Preliminary Examinations. A Scholarship, value £20, in Human Anatomy, for first-year students, to be awarded in April, 1876. A Scholarship, value £25, in Anatomy, Physiology, and Chemistry, for first-year students, to be awarded at the end of the session. Three Hospital Scholarships, value £20 each, for Clinical Medicine and Clinical Surgery (to be awarded in April), and Clinical Obstetrics (to be awarded in June); in connexion with the latter a prize of £5 will be awarded to the student who has attended most Midwifery cases for the hospital during the preceding twelve months.

The Duckworth Nelson prize, value £10, for Practical Medicine and Surgery (biennial). Money prizes to the value of £60 given annually by the House Committee for zeal in dressing out-patients and knowledge of Minor Surgery.

Appointments.—Four house-surgeoncies, tenable for three or six months, and dresserships to in-patients, open to all. Dresserships to out-patients, with the privilege of competing for the prizes above mentioned. Resident medical officer, tenable for two years, with a salary of £75 the first year and £100 the second year. Two junior resident medical officers, tenable for six months. Eight medical assistantships, held for three or six months, with residence and board in the hospital for three or six weeks. Resident accoucheur, tenable for six months. (N.B. The holders of all the resident offices are provided with rooms and board free of expense.) Four clinical assistants in the medical and surgical outpatient departments, each at a salary of £40. Medical registrar, salary £100. Surgical registrar, salary £100. Two prosectors of anatomy, ward clerks, and post-mortem clerks, according to merit.

General fee to lectures and hospital practice, 90 guineas, payable in two instalments of 45 guineas each. Library fee, £1 1*s*. Special entries can be made to lectures or practice.

St. Mary's Hospital.—There are four resident medical officers, three of whom are appointed for twelve months, and one, the obstetric officer, for six months, who board free of expense in the hospital. These appointments are awarded after competition, without additional fee. A resident registrar is also appointed from amongst the students, with a salary of £100 a year and dispensary fees, who resides free of expense in the hospital. In addition to the above, a demonstrator of anatomy is appointed annually with a salary of £100 a year; and the medical tutor in like manner, with a salary of £100 a year. Both these officers are eligible for re-election.

All general students are required to perform the duties of clinical clerks and dressers during the last two years of their curriculum. Students of the third year are also appointed to assist the physicians and surgeons in charge of the out-patients.

The Library is partly maintained by an annual grant from the school, and each student on entering is required to pay a fee of one guinea. There is a Hospital Medical Society, which meets regularly during the winter session.

A Maternity Department is attached to the hospital. There are special departments for Diseases of the Eye, the Ear, the Skin, and the Throat, in which clinical demonstrations are constantly given by the physicians and surgeons in charge of them.

Scholarships, Prizes, &c.—Three Scholarships in Natural Science, each tenable for three years, and of the value of £60 the first year, £40 the second, and £20 the third year, and an Exhibition in Natural Science of the value of £20, tenable for one year. One of the scholarships and the exhibition are awarded immediately before the commencement of each winter session, by open competitive examination. Two Extra Scholarships will also be awarded in October, 1875: one in Natural Science, tenable for three years, of the value of £60 the first year, £25 the second, and £15 the third, is restricted to students educated at Epsom College; the other is an Open Scholarship in Classics and Mathematics, tenable for one year, and of the value of £35. A Scholarship in Anatomy of the annual value of £20, for students who have completed their second winter session; and a Scholarship in Pathology of £20, for students who have completed their third winter session. Examinations will be held and prizes awarded in the various classes of each year at the termination of both the summer and winter sessions. Two prosectors are annually appointed, who each receive £5 and a certificate for their services.

Students can receive instruction in Vaccination.

Fee to the hospital practice and lectures, £89 5*s*. in instalments, or £84 in one sum; perpetual, £105 in instalments, or £99 15*s*. in one sum. Fee to the hospital practice and lectures required for the examination in Dental Surgery by the College of Surgeons, £52 10*s*. Special entries can be made to courses of lectures or periods of hospital practice. There is no fee for registration.

Middlesex Hospital.—There is a special Cancer Department, affording accommodation for 33 in-patients, whose period of residence in the hospital is unlimited. Special attention is bestowed on the clinical instruction of the students both in the wards and out-patient rooms. Classes, open to all the students, are held for practical instruction in the microscopic examination of healthy and diseased tissues, and also in the application of bandages and other surgical apparatus. Students are allowed to take out to read at their own homes the books from the large and carefully selected medical library of the school. Two Entrance Scholarships, of the annual value of £25 and £20, and tenable for two years, are offered for competition at the commencement of the winter session. Two Broderip Scholarships, of the annual value of £30 and £20, tenable for two years, and two clinical prizes (value six and four guineas respectively) are annually awarded to those students who pass the best examination at the bedside and the postmortem room. The Murray medal and Scholarship, in memory of the late Dr. John Murray, have been founded in connexion with the University of Aberdeen, and will be awarded every third year to a student of this hospital. The Governors' Prize of twenty guineas is also awarded annually to the student who shall most distinguish himself during his three years' curriculum. Valable class prizes are also given, and six resident clinical appointments are annually awarded, after competitive examination, to students who have completed their education, and complied with the regulations of the school. The officers thus appointed reside and board in the hospital free of expense. The College tutors assist all general students, especially those who are preparing for examination, free of charge; and their instruction is arranged with a view to avoid the necessity of students obtaining any private tuition, apart from that of the Medical School. The fee for attendance on the hospital practice and lectures required by the Colleges of Physicians and Surgeons and by the Society of Apothecaries is £90, which may be paid by instalments.

The clinical clerk and dresser of the physician and surgeon of the week dine at the board-room table, free of charge, with the view of their being constantly in the hospital to assist the resident-physician's assistant and house-surgeon in case of need, and to have the opportunity of seeing the fresh cases. A limited number of general students are also allowed to dine at the board-room table. The paid offices of medical registrar, surgical registrar, resident medical officer, and demonstrator of anatomy are open to qualified men as they become vacant. All clinical clerkships and dresserships are awarded without fee.

St. Thomas's Hospital.—*Prizes and Appointments for the year* 1875-6.—For First-year's Students: Two Scholarships, of the value of £60 and £40, will be awarded during the first week in October, after an examination in Physics, Chemistry, Botany, and Zoology; the William Tite Scholarship, founded by Sir William Tite, F.R.S., the proceeds of £1000 Consols, tenable for three years; also prizes of £20 and £10; summer, £15, £10, and £5. For Second-year's Students: The Musgrove Scholarship, founded by Sir John Musgrove, Bart., the President of the Hospital, and endowed with £1400 Consols, producing 40 guineas per annum, is awarded biennially to the student who shall take the highest place in the first class list in the examinations at the end of the second winter session; it is tenable for two years, provided the holder obtains a place in the first class in the subsequent examinations; making the winter prizes £42, £20, and £10; summer, £15, £10, and £5; with the dresserships and the clinical clerkships. For Third-year's Students: Prizes of £20, £15, and £10, and the Prosector's Prize of £5. Clinical clerks and dressers are selected according to merit. The Grainger Testimonial Prize of £20, awarded biennially to third or fourth year's students, for the best Physiological Essay, to be illustrated by preparations and dissections. The Cheselden Medal, for Surgery and Surgical Anatomy. The Mead Medal, founded by Mr. and Mrs. Newman Smith, is awarded annually to a third-year's student, in respect of a special Practical Examination in Medicine. The Solly Medal, with a prize of at least 10 guineas, will be awarded at the end of the session, to a student of the third, fourth, fifth, or sixth year, for the best Report of Surgical Cases. The Treasurer's Gold Medal, for general proficiency and good conduct. The house-physicians, house-surgeons, and resident accoucheur are chosen, from gentlemen who have obtained their professional diplomas, according to merit, and, with the dressers, are provided with rooms and commons. Two hospital registrars, at £40 per annum each, will be selected from gentlemen distinguished for merit.

Fee to hospital practice and lectures for the first and second year, each £40; £20 for the third; and £10 for each succeeding year; or £105 perpetual. The fee for attendance on the general subjects required of students in Dental Surgery is, for the two years, £45; or, by instalments, £40 for the first year, and £10 for the second.

University College, London.—The fees for lectures and hospital practice required by the Colleges of Physicians and Surgeons and the Society of Apothecaries during the student's entire course amount to £105 15*s.*, which may be paid as follows:—First winter, £36 5*s.*; first summer, £11 11*s.* Second winter, £32 1*s.*; second summer, £7 7*s.* Third winter, £7; third summer, £7 7*s.* Fourth winter, £4 4*s.*

Entrance Exhibitions.—Three Entrance Exhibitions, of the respective values of £30, £20, and £10 per annum, tenable for two years, are annually awarded, upon examination by printed papers, to gentlemen who are about to commence their first winter's attendance in a medical school. The subjects of the examinations are — Classics, Elementary Mathematics, Natural Philosophy, and either French or German at the option of the candidate. The next examination will take place at the College on September 28th and 29th. Notice of intention to compete, with a statement of the modern language in which the candidate wishes to be examined, must be left addressed to the Secretary, not later than 2 p.m. on September 18th, at the office of the College, where the regulations and copies of previous examination papers may be obtained.

Scholarships and Exhibitions.—The Atkinson Morley Surgical Scholarship, of £45, tenable for three years, is annually awarded to the student who, upon examination, is found to possess the greatest proficiency in the theory and practice of Surgery. The Sharpey Physiological Scholarship, of about £70 per annum, tenable for three years, for proficiency in Biological Science. Filliter Exhibition: a prize of £30 is awarded annually, in July, to the most proficient student in the class of Pathological Anatomy.

Medals and Prizes.—Dr. Fellowes' Clinical Medals, one gold and one silver, awarded at the end of each winter and summer session to pupils who have most distinguished themselves by reports and observations on the medical cases in the hospital. The Liston Gold Medal is awarded at the end of the summer session to the pupil who has most distinguished himself by reports and observations on the surgical cases in the hospital. The Alexander Bruce Gold Medal will be awarded for proficiency in Pathology and Surgery. The Cluff Memorial Prize is awarded every other year for proficiency in Anatomy, Physiology, and Chemistry.

Class Medals and Prizes.—Besides the above, gold and silver medals or other prizes are awarded in each class.

The appointment of assistant-curator to the Museum of Anatomy and Pathology, of demonstrators of anatomy, of resident medical officer to the hospital, and of surgical registrar—all of which have emoluments attached to them —are almost invariably conferred upon students of the College.

Offices in the Hospital tenable by Students. — Physicians' assistants, house-surgeons, midwifery assistants, physicians' clerks, surgeons' dressers, ward clerks, and ophthalmic surgeons' assistants are selected from the pupils, without additional fees.

Westminster Hospital.—The entry fee to lectures and hospital practice required by the Colleges of Physicians and Surgeons and the Society of Apothecaries may be paid in one sum of £80, or in two instalments—£42 and £40 at the commencement of the first two winter sessions, or in four instalments of £29 8*s.*, £14 14*s.*, £26 5*s.* and £13 13*s.*, at the commencement of the first four sessions.

In addition to the practice of the hospital, which contains 191 beds, the pupils of this school are admitted to the practice of the Westminster Ophthalmic Hospital, and to that of the National Hospital for Epilepsy and Paralysis.

A house-physician, house-surgeon, and resident obstetric assistant are appointed annually, by examination, from amongst the senior students, without the payment of any fee, and these officers are provided with board and lodging free of expense. The medical and surgical registrars receive each a salary of £40. The appointments of assistant house-surgeon, physician's assistant, surgeon's assistant, ophthalmic assistant, in-patients' clerks, in-patients' dressers, and out-patients' dressers, are open to students of the hospital.

Besides the prize appointments just enumerated there is a Scholarship in Anatomy and Physiology of twenty guineas, for second-year's men; an Exhibition in Anatomy and Elementary Physiology, of ten guineas, for first-year's men. There are also the Chadwick Prize for general proficiency, of the value of twenty guineas, and two Clinical Prizes of £5 each for Medicine and Surgery and practical work in the wards. Certificates of honour may be obtained in any of the classes. There are also two Entrance Scholarships of £20 and £10 each, tenable for two years. Examination in Latin, Mathematics, and French, German, or Greek, on October 2nd and 3rd.

Royal Free Hospital, Gray's-inn-road.—102 beds. Physicians: Dr. O'Connor, Dr. Cockle, Dr. Rickards. Surgeons: Mr. Victor de Méric, Mr. Fred. J. Gant, Mr. William Rose. This Hospital affords large opportunities for obtaining a bedside knowledge of medicine and surgery, also for the study of morbid anatomy. Students can prepare for examinations by attending a course of three or six months' clinical instruction. Vacancies for clinical clerks and dressers. For particulars apply to any member of the medical staff at the Hospital daily at 2 p.m.

Great Northern Hospital, Caledonian-road. — Consulting Surgeon: Frederick Le Gros Clark, Esq., F.R.S. Physicians: Dr. Leared, Dr. Hardinge, Dr. Cholmeley, Dr. Crucknell, Dr. Cook. Obstetric Physician: Dr. Gustavus C. P. Murray. Ophthalmic Surgeon: Mr. Bowater John Vernon. Surgeons: Mr. Gay, Mr. W. Adams, Mr. T. Carr Jackson, Mr. W. Spencer Watson, M. T. B. Lowne. Aural Surgeon: Mr. Harvey. Dental Surgeon: Mr. Charles James Fox. Chloroformist: Mr. George Eastes. House-Surgeon: Mr. P. N. Hart (Acting) M.B., M.R.C.S., C.M. Medical practitioners and students admitted to the practice of the hospital.

West London Hospital, Hammersmith-road, W.—68 beds. 407 in-patients. Consulting Physician: Dr. Henry Maudsley. Consulting Physician-Accoucheur: Dr. W. O. Priestley. Consulting Surgeons: Mr. Samuel Armstrong Lane and Mr. William Bird. Physicians: Dr. Goddard Rogers and Dr. Thorowgood. Physician for Diseases of Women: Dr. Wiltshire. Surgeons: Mr. William F. Teevan and Mr. Alfred Cooper. Surgeon for Diseases of the Eye: Mr. B. J. Vernon. Junior Physicians: Dr. Fish and Dr. Milner Fothergill. Junior Surgeons: Mr. J. A. Bloxam and Mr. H. T. Butlin. Surgeon-Dentist: Mr. H. E. Sewill. Analytical Chemist: Mr. William Crookes. Resident Medical Officers: Two House-Surgeons and an Apothecary. The practice of this hospital is open to all students and members of the medical profession. Gentlemen desirous of acting as clinical clerks or dressers can obtain all information on application to the secretary at the hospital.

Hospital for Consumption and Diseases of the Chest, Brompton.—Consulting Physicians: Dr. C. J. B. Williams, F.R.S., Dr. W. H. Walshe, Dr. R. P. Cotton, Dr. R. Quain, F.R.S. Consulting Surgeon: Sir William Fergusson, Bart. Physicians: Dr. J. E. Pollock, Dr. E. S. Thompson, Dr. C. T. Williams, Dr. R. D. Powell, Dr. J. Tatham. Assistant-Physicians: Dr. R. Thompson, Dr. B. Yeo, Dr. F. Roberts, Dr. T. H. Green, Dr. J. M. Bruce. Dental Surgeon: Mr. W. P. Bartlett. Resident Medical Officer: Mr. R. Rendle, F.R.C.S. Secretary: Mr. H. Dobbin. Three clinical assistants reside in the hospital for a period of six months. Pupils are admitted to the practice of the hospital: terms. £3 3*s.* for three months; perpetual, £5 5*s.* The medical practice of the hospital is recognised by the University of London, the Apothecaries' Company, and the Army and Navy and India Medical Boards. The hospital contains 257 beds, and there is an extensive out-patient department.

City of London Hospital for Diseases of the Chest, Victoria-park. Office: 24, Finsbury-circus, E.C.—Consulting Physicians: Drs. Peacock, J. Risdon Bennett, and Birkett. Physicians: Drs. Ward, Andrew, Thorowgood, and Sutton. Consulting Surgeon: Mr. J. Hilton. Assistant-Physicians: Drs. Shepherd, Smith, Corfield, and Berkart. Resident Medical Officer: Mr. Ernest O'Bark. Information respecting medical instruction at the hospital may be obtained on application to the physicians.

Royal Hospital for Diseases of the Chest, City-road, E.C.—Established 1814. 12 beds. Consulting Physicians: Drs. Herbert Davies and Horace Dobell. Physicians: Drs. H. H. Crucknell, G. Goddard Rogers, P. J. Hensley, Gilbert Smith, and W. S. Greenfield. Consulting Surgeon: Mr. J. Adams. Surgeon: Mr. Alfred Cooper. House Physician: (vacant). In-patients, 168; out-patients, 5199. It is proposed shortly to enlarge this hospital by addition of new buildings capable of holding 50 additional beds. The office of House-Physician, which is tenable for one year, and for which a sum of £100 is voted in lieu of board and residence, is filled up annually in October.

National Hospital for the Paralysed and Epileptic, 23, 24, and 25, Queen-square, Bloomsbury.—The physicians attend every Monday, Tuesday, Wednesday, and Friday, at half-past two o'clock. In and out-patients' practice and electrical-room treatment at that hour. Physicians: Drs. Ramskill, Radcliffe, Hughlings Jackson, and Buzzard. Assistant-Physicians: Dr. H. Charlton Bastian, Dr. Elam, Dr. Maclure, and Dr. Gowers. Surgeon: W. Adams, F.R.C.S. Medical Superintendent: Dr. Herbert Tibbitts. Medical Registrar: Dr. Sturge. Medical practitioners and students will be admitted on showing their cards.

Royal Orthopædic Hospital, 315, Oxford-street.—Surgeon: Mr. B. E. Brodhurst.—House-Surgeon: Mr. W. E. Balkwill. Secretary: Mr. Maskell. Operations on Mondays at 2 p.m. The hospital is open to all legally qualified practitioners. Pupils are admitted to witness the practice of the hospital on the following terms: Six months, £3 3s.; twelve months, £5 5s.; perpetual, £10 10s. The annual course of lectures will be duly announced.

Royal Westminster Ophthalmic Hospital, King William-street, Charing-cross.—The hospital contains 36 beds; and the patients, who number 10,000 annually, are seen, and operations performed, daily at 1 o'clock. The following are the days of attendance of the surgeons: Monday and Friday, Mr. Power and Mr. Rouse; Tuesday, Thursday, and Saturday, Mr. Hogg; Wednesday and Saturday, Mr. Cowell. The practice of the hospital is open to students. Fees for six months, £3 3s.; perpetual, £5 5s. Students of the hospital are eligible for the post of house-surgeon. Special Demonstrations and Lectures will be given during the summer session. Secretary, Mr. Farrant.

London School of Dental Surgery, Leicester-square.—Lectures are delivered in winter on Mechanical Dentistry, by Mr. James S. Turner, M.R.C.S., L.D.S., on Wednesdays, at 7 p.m.; on Metallurgy in its application to Dental Purposes, by Mr. G. H. Makins, M.R.C.S., F.C.S., on Tuesdays and Fridays, at 6.30 p.m. In summer, Mr. S. H. Cartwright, M.R.C.S., L.D.S., lectures on Dental Surgery and Pathology; and Mr. C. S. Tomes, M.R.C.S., L.D.S., on Dental Anatomy and Physiology (Human and Comparative). General fee for special lectures required for the curriculum, £15 15s.—Dental Hospital of London (in connexion with the above). Surgeons: Messrs. Fox, Underwood, Gregson, Coleman, Harding, and Hill. Assistant-Surgeons: Messrs. Moon, Medwin, Lane, Bartlett, S. H. Cartwright, and David Hepburn. Dental House-Surgeon: Mr. James Merson. Fee for two years' hospital practice required by the curriculum, £15 15s.

Seamen's Hospital (late *Dreadnought*), Greenwich, S.E.—This institution is established for the relief of seamen of all nations. Casualties are received at all hours. Apartments are provided in the hospital for students and others who may be desirous of studying diseases incidental to tropical climates before entering the services or going abroad. Unusually good opportunities also exist for the practice of operative surgery. Honorary Physician: Dr. George Budd. Visiting Physicians: Dr. Stephen H. Ward and Dr. Charles Henry Ralfe. Honorary Surgeon: Mr. Busk. Visiting Surgeon: Mr. Davies-Colley. Surgeon: Mr. W. Johnson Smith. House-Physician: Dr. J. T. Law. House-Surgeon: Vacant. Secretary: Henry C. Burdett.

The Hospital for Sick Children, Great Ormond-street, Queen-square, W.C., and Cromwell House, Highgate.—Physicians: Drs. Dickinson and Gee. Assistant-Physicians: Drs. W. B. Cheadle, O. Sturges, A. L. Galabin, R. J. Lee, and Thos. Barlow. Surgeons: Mr. T. Smith, Mr. F. Howard Marsh, and Mr. J. W. Haward. Surgeon-Dentist: Mr. T. Edgelow. Fee for three months' attendance, £3 3s.; perpetual, £5 5s. Secretary: S. Whitford. There are now 65 beds in the hospital, Great Ormond-street, and 52 beds at the country branch; total, 117. In-patients last year, 531; out-patients, 13,250. The practice at the hospital has recently been thrown open gratuitously to the pupils of the different hospitals and medical schools of London, on conditions which may be ascertained of the Secretary. The new hospital about to be opened will contain 110 beds.

Victoria Hospital for Children, Gough House, Queen's-road, Chelsea.—The hospital contains 54 beds, and has a large out-patient department; over 400 weekly. Physicians: Dr. Evans and Dr. Cavafy. Assistant-Physicians: Dr. Jones, Dr. Grigg, Dr. Laking, Dr. Pearson Irvine, and Dr. Allchin. Surgeon: Mr. Cowell. Assistant-Surgeons: Mr. Churchill and Mr. Fisher. Dental Surgeon: Mr. Risdon. House-Surgeon and Registrar, vacant. Secretary: Captain W. C. Blunt, R.N. Out-patients are seen daily as under:—Medical cases: Daily, except Saturday and Sunday, at 9 a.m.; and Mondays and Thursdays at noon. Surgical cases: Daily, except Saturday and Monday, at 10 a.m. Dental cases: Saturdays at 9.30 a.m.

Royal Infirmary for Children and Women, Waterloo-bridge-road.—Instituted 1816. Consulting Physicians: Dr. Wilks, Dr. John Williams. Consulting Surgeon: Mr. J. Cooper Forster. Physicians: Drs. G. V. Poore, W. Park, G. Roper, and E. J. Sparks. Surgeon: Mr. Edwin Canton. Surgeon-Dentist: Mr. Thomas Roberts. Resident Medical Officer: Mr. E. Overman Day. Secretary: Mr. W. Champion. Advanced students in medicine, and such practitioners as may desire it, are permitted to attend the practice of this hospital gratis. If a certificate signifying such attendance be required, the sum of five guineas must be paid to the physicians and surgeons in ordinary conjointly.

British Lying-in Hospital, Endell-street, St. Giles's, W.C.—Consulting Physician: Dr. Priestley. Consulting Surgeon: Sir William Fergusson, Bart. Physicians: Dr. Heywood Smith, Dr. Arthur Edis, and Dr. Wiltshire. Matron: Miss Freeman. Secretary: Mr. Vincent Yardley. This institution receives women only, as midwifery pupils. The pupils reside in the hospital, and attend the patients in-doors and within half a mile radius, under the direction of the matron and physicians. A course of lectures is also given by the physicians. The fee for the course of three months is ten guineas. Pupils that prove themselves competent receive a certificate signed by the physicians, enabling them to practise midwifery.

Belgrave Hospital for Children, 1, Cumberland-street, S.W.—Established 1866. 20 beds. Consulting Physician: Sir Wm. Gull. Consulting Surgeon: Mr. John Wood. Physicians: Dr. Farquharson and Dr. Fenwick. Surgeons: Mr. Brodhurst and Mr. Pick. Surgeon-Dentist: Mr. T. C. White. House-Surgeon: Mr. M. McHardy. In-patients, 97; out-patients, 900. Pupils are admitted to the practice of the hospital upon producing a certificate of being duly registered as medical students.

Evelina Hospital for Sick Children, Southwark-bridge-road, S.E.—Consulting Physician: Dr. Arthur Farre. Consulting Surgeon: Mr. Prescott Hewett. Physicians: Drs. C. Hilton Fagge, E. Buchanan Baxter, F. Taylor, and T. Crawford Hayes. Surgeons: Messrs. W. Morrant Baker, H. Howse, and R. Clement Lucas.

Pharmaceutical Society of Great Britain, Bloomsbury-square, W.C.—School of Pharmacy. The session will commence on October 1st, and extend to the end of July. Lectures on Chemistry and Pharmacy will be delivered by Professor Redwood on Monday, Tuesday, and Wednesday, at 9 a.m. Also lectures on Botany and Materia Medica, by Professor Bentley, on Thursday, Friday, and Saturday, at 9 a.m. A course of Systematic Botany will be delivered at the Royal Botanic Gardens, Regent's-park, during the summer months. The Laboratory, under the direction of Professor Attfield, is open from 10 a.m. to 5 p.m. daily, except Saturdays, when it is open from 10 a.m. to 2 p.m. Students may enter at any period during the session.

ENGLISH PROVINCIAL HOSPITALS AND MEDICAL SCHOOLS.

Queen's College, Birmingham.—The Sands Cox Prize, value £20, is annually awarded after examination in Medicine, Surgery, and Midwifery. The examination in 1876 will be held in the third week in March. The Warden's Prize, value £3 3*s.*, is awarded annually to the most proficient student of the first year. The Percy Prize, value £5 5*s.*, is awarded to the student who may pass the best examination in German. Class Prizes: Medals and certificates of honour are awarded annually in each class after examination. Hospital practice may be attended at either the General Hospital or the Queen's Hospital for a common fee. Composition fee, £50.

The General and Queen's Hospitals, Birmingham.—*The General Hospital*:—Consulting Surgeon: D. W. Crompton, F.R.C.S. Physicians: Dr. Fletcher, Dr. Russell, Dr. Wade, Dr. Foster, Dr. Rickards. Surgeons: Mr. Baker, Mr. Pemberton, Mr. Bartleet, Mr. Goodall, Mr. Jolly. *The Queen's Hospital*:—Consulting Surgeon: William Sands Cox, F.R.S. Consulting Surgeon-Accoucheur: Samuel Berry, F.R.C.S. Physicians: Dr. Heslop, Dr. Johnston, Dr. Sawyer, Dr. Mackey. Surgeons: Mr. West, Mr. Gamgee, Mr. Furneaux Jordan, Mr. Wilders. Obstetric Surgeon: Mr. John Clay. Acting Ophthalmic Surgeon: Mr. Priestly Smith. Pathologist: Mr. Thomas. Dental Surgeon: Mr. Charles Sims.

The practices of these hospitals are amalgamated for the purpose of clinical instruction under the direction of the Birmingham Clinical Board, by whose order all schedules will be signed and all examinations conducted. The hospitals have a total of upwards of 400 beds. 4500 in-patients, and 45,000 out-patients, are treated annually. Special instruction is given at the hospitals in the use of the microscope, laryngoscope, ophthalmoscope, in case-taking, and the art of prescribing. Practical Pharmacy is taught in the dispensaries of the hospitals.

Appointments.—At the General Hospital: A resident medical assistant, a resident surgical assistant, and two resident dressers; tenable for six months. At the Queen's Hospital: a resident obstetric assistant, tenable for six months. Resident surgical assistant; tenable for three months. Clinical prizes, of the value of £30, will be given annually.

Fees for attendance for four years (the period required by the University of London, and the Colleges of Physicians and Surgeons, &c.) on the Medical and Surgical Practice, and on the Clinical Lectures at both hospitals, £31 10*s.* This payment may be made in two equal sums, the first on entrance, and the second at the commencement of the second year.

All students will be required to attend six months alternately at each hospital, as they may be directed by the Clinical Board, excepting students who enter for six months only, who will be allowed to choose the hospital they wish to attend.

Any further information may be obtained from Robert Jolly, M.D., or William Thomas, M.B., Hon. Sec. of the Birmingham Clinical Board.

Bristol Royal Infirmary.—242 beds. Physicians: Drs. Fairbrother, E. L. Fox, Spencer, and Shingleton Smith. Surgeons: Messrs. Leonard, Tibbits, Steele, Board, and Dowson. Physician for the Out-patients: Dr. Waldo. Surgeon for the Out-patients: Mr. Bernard. House-Surgeon, H. M. Chute. Secretary: W. Trenerry. In-patients last year, 2678; out-patients last year, 23,923.

Fees.—Surgeon's pupil: First year, £12 12*s.*; two years, £21; three years, £26 5*s.* Dresser (extra fee): one year, £12 12*s.*; two years, £21; three years, £26 5*s.* Physician's pupil: six months, £8; one year, £15; eighteen months, £20; perpetual, £25. Each physician appoints a clinical clerk without extra fee. Each pupil is required to pay an entrance fee to the infirmary of £5 5*s.*, and a subscription of £1 1*s.* per annum to the library, which numbers about 2700 volumes, and contains most of the standard works on medicine and surgery, and also the medical periodicals.

Prizes.—Suple Prize: A gold medal, value £5 5*s.*, with £7 7*s.* in money, is given annually to each of the two successful candidates in the medical and surgical examinations. Clark's Prize: The interest of about £500 is given annually to the prizeman of the third year's examination at the Bristol Medical School, if educated at the Bristol Royal Infirmary.

Bristol General Hospital.—140 beds. Medical or Surgical Practice: Six months, £6; one year, £10; perpetual, £20. Library fee, £1 1*s.* per annum. Dressership or clinical clerkship, £5 5*s.* for six months. Two Scholarships of £15 each are awarded annually, and a Scholarship value £22 10*s.*, founded by the late John Naish Sanders, Esq., for the encouragement of the study of medicine and surgery by pupils in the hospital. Dressers reside in the hospital in weekly rotation free of expense. There is a large ward used solely as a children's ward.

Physicians: Drs. Martyn, G. F. Burder, and J. G. Swayne (*acc.*) Surgeons: Messrs. Coe, F. P. Lansdown, G. F. Atchley, and N. C. Dobson.

Bristol Medical School.—Prizes and certificates of honour are given after competitive examination amongst students of the first, second, and third years respectively. The interest of £500 will be given to the prizeman of the third year, who shall have been educated at the infirmary, and can produce certificates of good conduct and moral character.

Addenbrooke's Hospital, Cambridge.—Clinical Lectures in Medicine and Surgery in connexion with the Cambridge Medical School are delivered at this hospital twice a week during the academical year; and practical instruction in Medicine and Surgery, in the wards, is given by the physicians and surgeons daily, during the vacations as well as term time.

Leeds School of Medicine.—Attendance at the lectures of this school will confer the same qualifications for examination as are obtained in the medical schools of London. The Lectures on Chemistry, by Professor Thorpe, are delivered at the Yorkshire College of Science. The Hardwick Clinical Prize, value £10, is conferred annually upon the most deserving student who exhibits a satisfactory proficiency in Clinical Medicine. The Surgeons' Clinical Prize, value £10, given by the surgeons of the hospital, is conferred annually on the most deserving student who exhibits proficiency in Clinical Surgery. In addition to the Silver Medal awarded in Medical Jurisprudence, there is a prize of £10, for which a special examination is annually held. Practical Surgery and Practical Physiology are taught in accordance with the regulations of the Royal College of Surgeons. In the Infirmary there are six clinical clerkships and eight dresserships. Four resident assistants are chosen from the senior students; board and residence free. Besides the Infirmary there is a large Dispensary and a Fever Hospital; both are in the town, and open to students attending the School.

Liverpool Royal Infirmary School of Medicine.—Three house-surgeons and two house-physicians are elected every six months from pupils of the School who have obtained a qualification. Six dressers and six clinical clerks are elected quarterly. Pupils of the Infirmary are admitted to learn Pharmacy in the dispensing department for six months.

The Roger Lyon Jones Scholarship (£90) will probably be awarded during the next year.

The hospital contains 300 beds, including wards, with 40 beds, for the treatment of diseases of women. The Lock Hospital adjoining contains 60 beds.

Fees.—For six months' medical practice, five guineas; twelve months, six guineas; surgical, six guineas for six months, eight guineas for twelve months (this includes admission to the practice of the Lock Hospital adjoining the infirmary); perpetual medical and surgical practice, thirty-two guineas.

Liverpool Northern Hospital.—144 beds. A special ward for the diseases and accidents of children. Clinical lectures are regularly delivered by the physicians and surgeons during the winter and summer sessions. Instruction in Morbid Anatomy is given by the medical staff. Clinical clerkships and dresserships are open to all the students, without additional fee.

Fees for Hospital Practice and Clinical Lectures.—Perpetual twenty-five guineas; one year, ten guineas; six months, seven guineas; three months, four guineas.

One resident pupil received; fee, sixty guineas per annum. Attendance on the practice of this hospital qualifies for all the examining boards.

Liverpool Royal Southern Hospital.—Physicians: Dr. Cameron and Dr. Carter. Surgeons: Dr. Nottingham, Mr. Hamilton, and Dr. Wollaston. House-Surgeons: Mr. Henry Caddy and Mr. O. Gwatkin. 200 beds. Clinical Lectures given by the physicians and surgeons during the winter and summer sessions. Clinical Clerkships and Dresserships open to all students. A special ward for diseases and accidents of children. Rooms for a limited number of resident pupils.

Fees for Hospital Practice and Clinical Lectures.—Perpetual, twenty-five guineas; one year, ten guineas; six months, seven guineas; three months, four guineas.

The practice of the hospital is recognised by all the examining bodies.

Owens College (Manchester Royal) School of Medicine.—This medical school is located in a large, new building, which forms a part of Owens College. It is provided with a very large dissecting room, physiological laboratory, private laboratories, and work rooms, besides lecture rooms, a museum, and a library. The departments of Anatomy, Physiology, and Chemistry are taught by professors who devote the whole of their time to the duties of their respective chairs. The more strictly practical departments of medical study are taught partly in the Medical School and partly in the Royal Infirmary, to which are attached a fever hospital, a lunatic asylum, and a convalescent home. Medical and surgical clinical classes are conducted in the infirmary by the professors of medicine and surgery, and separate instruction is afforded in the elements of medical and surgical physical diagnosis, in obstetric medicine, ophthalmic surgery, and pathological anatomy by the different members of the staff of the Medical School and Infirmary. The following scholarships and prizes are open to students of the Medical School:—1. A Scholarship and Prizes are awarded at the end of each academic year to students of the first, second, and third year. 2. A Platt Physiological Scholarship of £50 a year for two years is offered annually to the student who, having studied for one entire session in the physiological laboratory of Owens College, has prosecuted the best original investigation in Physiology and has passed a satisfactory examination in Physiology. 3. A Dumville Surgical Prize of £20 is offered annually for proficiency in Clinical Surgery. 4. Medical and Surgical Clinical Prizes, each of the value of six guineas, are open to competition each year for the best reports (with comments) of cases which have occurred in the wards of the infirmary.

University of Durham.—College of Medicine, Newcastle-upon-Tyne.—*Winter Session* (commencing Oct. 1st, 1875).—Physiology: The Professor of Physiology and Biology about to be appointed by the Colleges of Medicine and Physical Science. Anatomy: Dr. Nesham, Dr. Armstrong, and Mr. Russell. Medicine: Dr. Philipson. Surgery: Dr. Heath. Chemistry: Mr. Marreco, M.A.—*Summer Session.*—Midwifery: Dr. Gibson. Botany: Mr. H. E. Armstrong. Medical Jurisprudence: Dr. Bramwell. Therapeutics: Dr. Humble. Materia Medica: Dr. Arnison. Practical Chemistry: Mr. Marreco, M.A. Operative Surgery: Dr. Heath. Pathological Anatomy: Dr. Gibb. Pharmacy: Mr. Proctor. Practical Physiology: the Professor of Physiology. Medical Tutor and Demonstrator: Dr. Reoch, M.A., M.B., M.C.

Fees for Lectures.—Composition fee for all the Lectures, qualifying for the Licence in Medicine and the Mastership in Surgery of the University of Durham, the Licence and Membership of the Royal College of Physicians, the Membership of the College of Surgeons, and the Licence of the Apothecaries' Society, and payable on entering to the first winter session, £52 10*s.* Perpetual ticket for Pharmacy curriculum, £12 12*s.* Separate courses of lectures, each £4 4*s.* Single course of Chemistry, £5 5*s.* The composition fee entitles the holder to attend the lectures on Botany, Chemistry, Materia Medica, and Pharmacy, and to use the Museum of Materia Medica in the Library of the College.

Hospital Practice.—This can be attended at the Newcastle Infirmary, which contains 230 beds. Midwifery, Diseases of the Eye, and Insanity can be specially studied. The Laboratories, Libraries, and Museums are open daily.

Fees for Hospital Practice.—Twelve months, £7 7*s.*; six months, £5 5*s.*; three months, £4 4*s.*; perpetual fee, £17 17*s.*; or, if paid by instalments, first year £7 7*s.*; second year £6 6*s.*; third year, £5 5*s.* These fees are payable in advance.

Medical Scholarships in the University of Durham.—Four Scholarships of £25 a year each, tenable each for four years, and four resident Dresserships, are conferred for merit. The resident dressers, who also act as clinical clerks, pay £10 10*s.* for six months' board in the hospital. Dickinson Memorial Scholarship, £15, tenable for one year, for general proficiency.

Newcastle-upon-Tyne Infirmary.—230 beds. Medical and Surgical clinical lectures are delivered, and clinical instruction is given in the wards. There are special wards for the treatment of children, ophthalmic and syphilitic diseases. Physicians: Dr. Embleton, Dr. Philipson, and Dr. B. Bramwell. Surgeons: Dr. Heath, Mr. Russell, Dr. Arnison, and Dr. L. Armstrong. Assistant-Surgeons: Mr. A. Bell, Dr. Hume, and Mr. J. Hawthorn.

Fees for Hospital Practice and Clinical Lectures.—Twelve months, seven guineas; six months, five guineas; three months, four guineas. Perpetual fee, seventeen guineas; or, if paid by instalments, first year, seven guineas; second year, six guineas; third year, five guineas. These fees are to be paid on entering at the hospital.

Four resident clinical assistants are nominated by the Medical Board half-yearly; and, if approved, are appointed by the House Committee. The clinical clerks and resident dressers are provided with apartments, and pay a fee of £10 to the hospital for their board. These appointments are made without any extra fee.

Eye Infirmary, Newcastle-on-Tyne.—The Eye Infirmary last year was completely renovated, and is furnished with all the latest instruments for diagnosis and treatment of eye disease. 300 operations in Ophthalmic Surgery are performed annually.

Norfolk and Norwich Hospital.—120 beds. One year's attendance recognised by examining boards. Fees: For the physicians' practice, ten guineas, perpetual. For the surgeons' practice, including dressership, £20 for one year; £30 for two years; and £40 perpetual. Pupils resident and non-resident. Physicians: Dr. Copeman, Dr. Eade, and Dr. Bateman. Hon. Consulting Surgeon: Mr. Nichols. Surgeons: Mr. Firth, Mr. Cadge, and Mr. Crosse. Assistant-Surgeons: Mr. Williams and Dr. Beverley.

Sheffield School of Medicine.—The Infirmary contains 200 beds; a Museum of Pathology, Library, and Post-mortem Theatre, with microscopes, and all the appliances for clinical research. Perpetual fee for attendance on all the lectures required by the Royal College of Surgeons and the Apothecaries' Hall, £42. Prospectuses and all further information may be obtained upon application to the Hon. Secretary, Mr. A. Jackson.

Sheffield Public Hospital and Dispensary.—Physicians: Dr. J. C. Hill, Dr. Law, and Dr. H. J. Branch. Surgeons: Mr. Jackson, Dr. Keeling, and Mr. Thorpe.

Sheffield Hospital for Women, Figtree-lane.—Medical officers: Dr. Jackson, Dr. Keeling, Dr. Hime, and Mr. F. Woolhouse. The hospital is devoted more especially to cases requiring obstetric operations and difficult midwifery. Out-patients are attended daily at the hospital. Midwifery cases are attended at their homes by the hospital midwives. Students can attend the practice of the hospital, and be supplied with cases of midwifery, on payment of a fee of one guinea.

North Staffordshire Infirmary, Hartshill, Stoke-upon-Trent.—The New North Staffordshire Infirmary was opened in 1869, and is built on the pavilion plan. It has accommodation for nearly 200 patients. In-patients last year, 1199; out-patients, 5416. The hospital is duly recognised by the Court of Examiners of the Royal College of Surgeons of England, and students have great facilities for acquiring a practical knowledge of their profession.

Wolverhampton and Staffordshire General Hospital.—210 beds. Attendance recognised by examining boards. Pupils resident and non-resident. The hospital contains large male and female accident wards, general medical and surgical wards, a children's ward, a ward for diseases of women, and a fever wing. The out-patient department, commodious and convenient, is semi-detached from the main building.

Fees for Hospital Practice.—One year, ten guineas; perpetual, twenty guineas. The fees must be paid to James Hay, Esq., secretary to the hospital. Physicians: Dr. Millington and Dr. Totherick. Surgeons: Mr. Vincent Jackson, Mr. J. O'Brien Kough, and Mr. C. A Newnham. House-Surgeon: Mr. C. L. Taylor. House-Physician: Charles A. Nankivell, M.B. Lond. Operations are performed in the theatre every Thursday morning at 11 o'clock.

York County Hospital.—Established 1740; rebuilt 1851. 100 beds. In-patients, 748; out-patients, 3229. Physicians: Drs. G. Shann and W. Matterson. Surgeons: Messrs. W. D. Husband, G. Hornby, and R. Hewitson. House-Surgeon: Mr. Samuel Wreford. Secretary: Mr. R. Holtby.

SCOTTISH HOSPITALS AND MEDICAL SCHOOLS.

Royal Infirmary, Edinburgh.—Beds are set apart for clinical instruction by the professors of the University of Edinburgh. Courses of Clinical Medicine and Surgery are also given by the ordinary physicians and surgeons. Special instruction is given in the medical department on Diseases of Women, Physical Diagnosis, &c., and in the surgical department on Diseases of the Eye. Separate wards are devoted to fever, venereal diseases, diseases of women, diseases of the eye, also to cases of incidental delirium or insanity. Post-mortem examinations are conducted in the Anatomical Theatre by the Pathologist, who also gives practical instruction in Pathological Anatomy and Histology. Hospital tickets: Perpetual in one payment, £10; annual, £5 5*s.*; half-yearly, £3 3*s.*; quarterly, £1 11*s* 6*d.* Separate payments for two years entitle the students to a perpetual ticket. No fees are payable for any medical or surgical appointment. The subordinate appointments are open to all students and junior practitioners holding the hospital ticket during the period over which the appointment extends. These appointments are as follows:—1. Resident physicians and surgeons are appointed, and live in the house free of charge. Candidates must be registered as legally qualified practitioners. The appointment is for six months, but may be renewed at the end of that period by special recommendation. 2. Non-resident clinical clerks are appointed by the physicians and surgeons for such periods and under such conditions as they deem expedient. 3. Dresserships: Each surgeon appoints from four to nine dressers, the appointment being for six months. 4. Assistants in the Pathological department are appointed by the pathologist.

School of Medicine, Edinburgh.—The lectures qualify for the University of Edinburgh and the other universities; the Royal Colleges of Physicians and Surgeons of Edinburgh, London, and Dublin, and the other medical and surgical boards.

In accordance with the statutes of the University of Edinburgh, any four of the medical classes required for graduation, or two complete *anni medici*, may be attended in this school, each of which *anni medici* may be constituted by attendance on two of the six months' courses, or on one of these and two three months' courses. The regulations require that the fee for any class taken for graduation in Edinburgh shall be the same as that for the corresponding class in the University.

The whole of the education required for graduation at the University of London may be taken in this school.

The minimum cost of the education in this School of Medicine for the double qualification of physician and surgeon from the Royal Colleges of Physicians and Surgeons, including the fees for the joint examination, is £90 4*s.*, which is payable by yearly instalments during the period of study; whilst the minimum cost for the single qualification of either physician or surgeon, including fees for examination, is £80.

Edinburgh Eye Infirmary, 6, Cambridge-street, Lothian-road.—Number of beds, 6. Surgeons: Mr. B. Bell and Dr. Joseph Bell. Assistant-Surgeon: Dr. Kirk Duncanson. Three months' attendance fee, £1 1*s.* Instruction in the use of the Ophthalmoscope is given. Hour of visit, 1 to 2 daily. Average number of out-patients, 900 to 1000.

Royal Hospital for Sick Children, Meadowside House, Edinburgh.—Consulting Physicians: Professor Sir Robert Christison, Bart., Drs. Charles Wilson, Graham Weir, and Matthews Duncan. Consulting Surgeon: Professor Spence. Pathologist: Professor Sanders. Ordinary Physicians: Drs. Ritchie, Linton, and James Dunsmure, jun. Extra Physicians: Drs. James Andrew and James Cumming. Assistant Extra Physician: Dr. Ballingall. Surgeon-Dentist: Dr. Smith. Ophthalmic Surgeon: Dr. Argyll Robertson. Resident Physician: Dr. James Crabb. Honorary Secretary: Mr. John Henry, 20, St. Andrew-square.

Fees.—To hospital, three months, £1 1*s.*; to dispensary department, three months, £1 1*s.*

Anderson's University, Glasgow.—The winter session will be opened on Tuesday, October 27th; the summer session on the first Tuesday of May. Anatomy, Professor A. M. Buchanan, M.D.; Chemistry, Professor ———; Institutes of Medicine (Physiology), Professor E. Watson, M.D.; Surgery, Professor Dunlop, M.D.; Materia Medica, Professor Morton, M.D.; Practice of Medicine, Professor Wood Smith, M.D.; Midwifery (in summer), Professor J. G. Wilson, M.D.; Medical Jurisprudence (in summer), Professor Alexander Lindsay, M.D.; Botany (in summer), Mr. Hennedy; Ophthalmic Medicine and Surgery, Dr. Wolfe.

Class Fees.—For each of the above courses of lectures, first session, £2 2*s.*, second session, £1 1*s.*; afterwards free. Anatomy Class Fees: For both courses (lectures and demonstrations on Practical Anatomy), first session, £4 4*s.*; second session, £4 4*s.* The dissecting-room is free for two sessions to those who attend both courses of Anatomy. After the second year the fee for admission to the dissecting-room is £1 1*s.* per session.

The fee for all the lectures in the Medical School required of candidates for the diplomas of physician and surgeon amount to £30.

Diploma in Medicine and Surgery.—Gentlemen who have studied in this School are eligible for examination before any of the Royal Colleges, and in Glasgow they may obtain the diplomas of physician and surgeon or general practitioner, which entitles to registration under the Medical Act, with the right to practise Medicine and Surgery in any part of the kingdom.

Glasgow Royal Infirmary.—583 beds. Physicians: Drs. Scott Orr, Perry, M'Laren, J. Wood Smith, and M. Charteris. Surgeons: Drs. Morton, E. Watson, Dewar, J. Dunlop, and H. C. Cameron. Besides the clinical instruction given at the bedside, lectures on the cases are given four times weekly, at 9 a.m., during the winter and summer sessions. The Pathological Museum is open to students. There are five physicians' and five surgeons' assistants, who perform all the duties of house-physicians and house-surgeons. They are lodged and boarded in the hospital for £25 per annum. There is also a Fever assistant, who receives a salary of £25, and is boarded free. Dressers to the surgical wards and clerks to the dispensary are appointed without fee.

Aberdeen Royal Infirmary.—Contains about 300 beds. Consulting Physician: Dr. A. Harvey. Physicians: J. W. F. Smith-Shand, R. Beveridge, Angus Fraser. Consulting Surgeon: Mr. D. Fiddes. Surgeons: Messrs. W. Pirrie, D. Kerr, A. Ogston, and J. O. Will. Ophthalmic Surgeon: Dr. Alex. D. Davidson. Pathologist: Dr. James Rodger. Dental Surgeon: Mr. Williamson. Resident Superintendent and Apothecary: Dr. R. Rattray. Resident Assistant-Physician: Mr. James Smith, A.M. Resident Assistant-Surgeon: Mr. James Simpson. Pathologist and Curator of Museum: Dr. J. Rodger. Treasurer and Secretary: Mr. W. Carnie.

The Aberdeen Royal Lunatic Asylum.—Contains about 475 beds. Resident Physician and Clinical Teacher: Dr. Robert Jamieson. Consulting Physician: Dr. John Macrobin.

IRISH HOSPITALS AND MEDICAL SCHOOLS.

Queen's College, Belfast.—*Fees:* Anatomy and Physiology, first course, £3; each subsequent course, £2. Anatomic Demonstrations and Practical Anatomy, each course, £3. Practical Chemistry, £3. Other Medical lectures: first course, £2; each subsequent course, £1.

Belfast Royal Hospital.—Physicians: Drs. Purdon, Smith, Ross, and Professor Cuming. Surgeons: Drs. Browne, Murney, James Moore, and John Moore. There is an extern department for the treatment of diseases and injuries not admitted into the hospital. Four pupils are permitted to enjoy the advantages to be derived from residence in hospital; £30 per annum is charged for board, &c. *Fees* —For Clinical Instruction, including hospital fees and 10*s.* 6*d.* registration fee at the beginning of each session: First winter session, five guineas; second, five guineas; third, five guineas; fourth and afterwards, one guinea. First, second, and third summer sessions, £2 12*s.* 6*d.*; fourth session and afterwards, £2 12*s.* 6*d.* Perpetual fee, £10 10*s.*, payable in two instalments.

The Malcolm Exhibition is competed for annually in May by the students attending this hospital.

Sir Patrick Dun's Hospital, Dublin.—Consulting Physician: Dr. W. Stokes. Consulting Surgeon: Dr. Wm. Collis. Physicians: Dr. J. M. Purser, Dr. W. Moore, Dr. Aquilla Smith, Dr. E. B. Sinclair. Surgeons: Dr. Thos. Evelyn Little, Dr. Ed. H. Bennett, Dr. R. G. Butcher, Dr. Ben. McDowel. Hospital fee for twelve months, including nine months' Clinical Lectures, £9 9*s.*

Richmond (Surgical), Whitworth (Medical), and Hardwicke (Fever) Hospitals, North Brunswick-street, Dublin.—These hospitals contain 312 beds, and have attached to them the Carmichael School of Medicine, a new building, with large dissecting-rooms, museums, and where lectures are given on all the different branches of Medicine and Surgery. Two clinical lectures are delivered in each week, in addition to the usual bedside instruction, which is given daily by the physicians and surgeons. A large Dispensary is attached to both the Medical and Surgical Hospitals, where patients are seen daily. Average daily attendance last year, 150. Practical Pharmacy is taught under the superintendence of the apothecary of the hospitals. A house-surgeon is appointed every second year; he holds the appointment for two years, and receives a salary. Eight resident clinical clerks are appointed each half-year, and provided with furnished apartments, fuel, &c. The Richmond Institution for the Insane, containing 1000 patients, adjoins these hospitals, affording every facility for the study of mental diseases.

Carmichael School of Anatomy, Medicine, and Surgery, North Brunswick-street, Dublin (in immediate proximity to the largest hospital in Ireland). Open for dissections 1st October. Lectures begin 1st November. Premiums to the value of £60 are awarded at the end of the session; and the Mayne Scholarship, value £15, will be given for proficiency in purely Practical Medicine, Surgery, and Anatomy, as tested by clinical examinations in the hospitals and by operations and dissections on the subject. Registrar: Dr. Harvey, 7, Upper Merrion-street, Dublin.

Dr. Steevens's Hospital and Medical College.—Operations on Saturday at ten. Six months' attendance, seven guineas; nine months', nine guineas. Lectures and Hospital Practice, College and Hall, seventy-eight guineas, in two instalments. The hospital contains 250 beds.

Ledwich School of Surgery, Peter-street, Dublin.—All the several courses of lectures required by the various licensing bodies to entitle the student to present himself for examination are delivered in the theatre of the institution, and are fully recognised. The school is in a central situation and in the immediate vicinity of four great medical and surgical hospitals, thus affording to the student the most ample opportunity of acquiring a thorough knowledge of the symptoms and treatment of disease. Demonstrators will be present in the dissecting-room at all hours. At the termination of the sessions, prizes will be awarded to the best answers in each department. Applications to be made to Edwd. Ledwich, Sec., 7, Harcourt-street, Dublin, from whom all particulars in connexion with the institution may be obtained.

EDUCATIONAL VACCINATING STATIONS.

In order to provide for the granting of those special certificates of proficiency in vaccination which are required to be part of the medical qualification for entering into contracts for the performance of public vaccination, or for acting as deputy to a contractor, vaccinating stations in London and the large towns are open, under certain specified conditions, for the purposes of teaching and examination. The public vaccinators officiating at these stations are authorised to give the required certificates of proficiency in vaccination to persons whom they have sufficiently instructed therein.

MEDICAL TEACHERS.

The Drs. Power continue daily their Classes for the various Competitive and Pass Examinations. Dr. Power receives two Resident Pupils. Dr. W. H. Power prepares Senior Practitioners by correspondence for the M.D. St. And. and the Colleges of Physicians Lond. and Edin. — Lecture-rooms, 8, Red Lion-square, Holborn, W.C.

Mr. Thomas Cooke, F.R.C.S., Senior Assistant-Surgeon to the Westminster Hospital, continues his Lectures and Demonstrations of Anatomy and Physiology at his Private Licensed Dissecting-room, 102, Stamford-street, Waterloo-bridge.—16, Woburn-place, Russell-square.

Dr. W. Handsel Griffiths, Lecturer on Chemistry, Ledwich School of Medicine, Dublin, and Librarian, Royal College of Surgeons in Ireland, has Classes on Materia Medica, Chemistry, Botany, and Medical Jurisprudence, preparatory for the Universities, Royal Colleges of Physicians and Surgeons, Apothecaries' Hall, and Public Services.—Laboratory, Ledwich School of Medicine, Peter-street, Dublin.

Mr. Thomas Lyle, F.R. Hist. S. (of the University of London), prepares gentlemen for the Preliminary Arts Examination of the Apothecaries' Hall and the Royal College of Surgeons, and for the Matriculation at the London University. Resident Pupils received. During the year 1874 thirty students were successful, many of whom obtained honours.—Fern House, 48, Navarino-road, Dalston, N.E.

Mr. Murray, B.A., Arkteon House, Wray-crescent, Tollington-park, Holloway, N., prepares for the Preliminary Examination at the Royal College of Surgeons and Apothecaries' Hall, and the Matriculation at the University of London.

Dr. Coales, LL.D., M.A., prepares candidates in Class or by Private Lessons for the following examinations: London University, Preliminary Scientific and Matriculation: College of Surgeons, Preliminary Membership and Fellowship; Apothecaries' Hall, Preliminary Membership. Resident Pupils received.—119, Gower-street, W.C.

Mr. F. A. Hanbury, M.A., Wrangler and late Senior Scholar of his College, prepares Pupils for the Matriculation Examination of the London University, for the Preliminary Examination of the Royal College of Surgeons, &c.—24, Old-square, Lincoln's-inn, W.C.

Mr. Henry Sergeant, B.A., 8, High-street, Camden-town, N.W., prepares gentlemen for the London University Matriculation; also for Royal College of Surgeons, Apothecaries' Hall, British Pharmaceutical Society, &c.

Mr. Wm. Youldon, C.M., prepares candidates for the College of Surgeons, the Apothecaries' Hall, and likewise for the Entrance Scholarships for the London, Charing-cross, and other Metropolitan Hospitals, privately, in class, or by letter.—64, Grafton-street, Mile-end, E.

Mr. S. Elliott, B.A., Rochester-row, S.W., prepares candidates for Matriculation, Preliminaries of the College of Surgeons, Apothecaries Hall, &c., either privately, in class, or by letter.—Terms on application.

Mr. G. Hind will continue his Demonstrations, commencing on the 15th inst., at 11 A.M., at 29, Newman-street, Oxford-street.

Mr. F. A. White, B.A. (Classical and Mathematical Honours, Cambridge), prepares pupils for the Matriculation at the London University, and for the Examinations at the Royal College of Surgeons and Apothecaries' Hall.—178, Alexandra-road, St. John's-wood, N.W.

A TABULAR VIEW OF THE DAYS AND HOURS OF THE INTRODUCTORY LECTURES

To be delivered at the different Medical Schools.

	Lecturers.	Days and Hours.
St. Bartholomew's Hospital		Oct. 1st
Charing-cross Hospital	Mr. W. Fairlie Clarke	„ 1st, 4
St. George's Hospital	Dr. Barnes	„ 1st, 4
Guy's Hospital	Dr. Thos. Stevenson	„ 1st, 2
King's College	Dr. Curnow	„ 1st, 4
London Hospital	Dr. W. B. Woodman	„ 1st, 3
St. Mary's Hospital	Dr. Randall	„ 1st, 8
Middlesex Hospital	Mr. B. Thompson Lowne	„ 1st, 4
St. Thomas's Hospital	Dr. Payne	„ 1st, 3
University College	Professor Corfield	„ 1st, 3
Westminster Hospital	Mr. R. Davy	„ 4th, 3
Glasgow University	Prof. G. Buchanan	„ 26th, 12
Durham University	Dr. G. Y. Heath	„ 1st, 2
Queen's College, Birmingham	Rev. W. H. Poulton	„ 1st, 3
Leeds School of Medicine	Mr. T. R. Jessop	„ 1st, 4
Liverpool Royal Inf. and Sch. of Med.	Dr. Dickinson	„ 2nd, 3
School of Medicine, Bristol		„ 1st
Sheffield School of Medicine	Dr. J. Young	„ 1st, 4
Edinburgh University	Sir Alex. Grant	Nov. 1st, 2
Liverpool Southern Hospital		Oct. 1st
Owens College, Manchester		„ 1st
Aberdeen University		Oct. 18th
Anderson's University, Glasgow		„ 26th

TO CORRESPONDENTS.

Our thanks are due to those gentlemen who have kindly supplied us with the requisite information relative to the various medical examining bodies, hospitals, and medical schools given in this Students' Number of The Lancet.

In consequence of the present number being exclusively devoted to information especially interesting to students, reference to other subjects is necessarily postponed until next week.

Clinical Lecture

ON

SOFT CHANCRES IN THEIR RELATION TO SYPHILIS.

By JONATHAN HUTCHINSON, F.R.C.S.,
SENIOR SURGEON TO THE LONDON HOSPITAL,
SURGEON TO MOORFIELDS OPHTHALMIC HOSPITAL AND TO THE HOSPITAL FOR SKIN DISEASES.

GENTLEMEN,—I wish to state to you, as explicitly as I can, my creed as to the relationship between the soft and the hard chancre. It is simply this: that the one is produced by pus-contagion, and the other by a specific virus. Let me ask you for the time to try to conceive of the latter as of the sporules of yeast, or as of some infinitely minute molecular bodies possessing independent vitality, and capable of growth and of enormously prolific multiplication when once implanted in a suitable soil. Although the cryptogamic or microphytic character of the syphilitic virus has never been yet demonstrated, yet it is so highly probable that we conveniently assume it proven. At any rate it is essential that you should think of its germs as of specific and definite bodies—as definite, for instance, as the seeds of clover or mustard, and as capable of being mixed up with other materials whilst yet preserving intact their own individuality. Now, let us ask what is our knowledge as to the results of implantation of these germs in the human body. We know this, that usually for a day some trivial irritation marks the spot where the inoculation has taken place, that this irritation soon passes off, and that all appears quite well for about a month or five weeks, when the spot begins to itch, to become red, and subsequently to indurate. A little later we find a peculiar hardness at the base of the inflamed spot; and to this hardness, attended as it usually is by but little ulceration or discharge, we give the name of the Hunterian chancre. We know, further, that at about the time when the sore takes on characteristic induration the patient usually becomes a little feverish, his tonsils ulcerate, and his skin shows numerous spots or blotches, symmetrically placed. Such is the usual, or perhaps we might say the typical, course of primary and secondary syphilis; but we know also that departures often occur from this type. The qualities in the specific virus which cause induration in the chancre may also cause inflammation of a more destructive kind, and then the sore, instead of remaining almost free from ulceration and suppuration, becomes deeply eroded by molecular gangrene, and may discharge purulent secretion in some abundance. This liability to ulcerate occurs not alone in the primary sore or chancre, but in the papules or tubercles which constitute the secondary rash. These are often quite free from secretion, their epidermis never breaking; but in many cases they ulcerate, and become covered by a pus-crust.

You must now allow me to reiterate a very important assertion as to fact which I have often before made, and it is this—that *all living pus is contagious*. I mean that all living pus-cells possess the power of setting up when transferred to another home, if that home be a suitable one, a kind of inflammatory action similar to that from which they themselves had originated. Gonorrhœa-pus will produce gonorrhœal inflammation; but note, it must gain a favourable tissue home. It will succeed if put on the mucous membrane of the urethra, or on the conjunctiva, or into the nostril, or into the rectum, but in each of these parts it flourishes with differing degrees of vigour, whilst on the skin, and possibly in the mouth, it will not live at all. The doctrine of the contagiousness of freshly-produced (i. e., living) pus explains much that we observe as to the spread of many forms of skin disease in which the secretion infects other parts of the patient's skin or the skin of other persons. We have long been in the habit of applying the old term porrigo to all forms of eruption believed to be due to the transference of purulent secretion from part to part. Foot-rot in sheep is another excellent example of the contagiousness of pus, this disease being simply a kind of suppurating whitlow of the hoof, which spreads through a flock by contagion from one to another. There are several secondary laws which we must keep in mind in reference to the contagiousness of pus. First, I have already said that the pus, if it is to grow on the new soil, must be living when you put it there. This is obvious. You must not expect the pus of an abscess, for instance, which is usually dead and in an advanced state of fatty degeneration, to manifest any vital properties. It may possibly irritate, but it can do nothing worse. Secondly, the precise character and stage of the inflammatory process which has produced the pus will be represented in the recipient. If you inoculate the conjunctiva with the pus from gonorrhœa in an early and acute stage, an acute purulent ophthalmia will result quite different from that which would follow inoculation with pus from a chronic gleet. Thirdly, it seems very probable that the pus produced by any special tissue is contagious, or, in other words, capable of further vital action, by preference on some tissue of similar kind to that in which it originated. I have already mentioned gonorrhœa-pus as an instance, and alluded to its different degrees of virulence on the different mucous surfaces. We may remember, in passing, that gonorrhœa of the male urethra rarely causes similar inflammation on the mucous lining of the prepuce, whilst in the female gonorrhœal suppuration of the vagina almost always infects the urethra. We may venture, I think, to believe, without much fear of being wrong, that pus-cells, as a rule, prefer that their new habitat should resemble their birthplace. The negro does not thrive in Newfoundland, nor the Esquimaux on the Gold Coast, although each might bear without detriment transference to almost any distance from home if to a home-like country. It is so with pus-cells: those originating in the skin are contagious to skin, those in the glans to the mucous membrane of the glans, those from the urethra to the urethra, and so on.

The bearing of these facts upon the theory of venereal sores is obvious. We have seen that the true virus of syphilis may cause inflammation, and thus result in ulceration and the formation of pus. Let me ask you to believe that the pus so produced is in itself contagious, and you have my theory of all soft or non-infective chancres. This pus, although produced by an inflammation caused by the specific germs of syphilis, does not necessarily contain those germs. It may contain them, or it may not, just as the clover you sow in your field may or may not contain, as an accidental admixture, the seeds of poppy as well. If the poppy-seeds be there they will probably grow; and just so if with the pus-cells there be also the germs of the syphilitic virus, they too may grow, and you may have a mixed crop. Mixed chancres are indeed very common. I hope I shall mislead no one by using the illustration of the clover and poppy-seed, which is, after all, only superficially applicable. The difference between the contagion of pus—a purely local affair—and that of syphilitic virus, a zymotic, self-multiplying, specific poison, capable of passing into the blood, and destined to go through long stages of development and change, is far greater than any that can be imagined between two species of vegetable seeds. Nor have we, in mentioning these points of great difference, specified the chief, which is that the relationship between the syphilitic virus and the pus-cells is that of producer and product—one which no two vegetable seeds ever maintain to each other. If they were like each other in any degree comparable to the likeness between two seeds, even of the most widely different plants, there would be some show of reason for the terms employed by dualists. On the contrary, I hold that the dualists have not, and never had, the slightest basis for their creed. Chancres differ, it is true; but we have, and let us be thankful that it is so, no duality of syphilis. The soft sore is not syphilis at all, and cannot produce syphilis; nor is it the offspring of a sister virus. If the term dualism means anything it must, I suppose, mean this—that there are extant two kinds of specific poison, each producing its specific results, and incapable of transmutation or alliance. If the hypothesis which I have suggested be the true one the soft sore is not the offspring of a specific virus, but comes as a sort of side result from the inflammation caused by it. Thus, if you could to-day exterminate soft sores, and destroy all the secretions capable of producing them by contagion, you must expect in a few weeks again to find them reproduced.

If, on the other hand, you could destroy all hard chancres, and all the specific germs of syphilis, there would be no reproduction of the disease. The soft sore cannot develop the specific germs of syphilis; but the germs of syphilis can cause the inflammatory action which produces the pus that is the *materies morbi* of the soft sore. I repeat, there is no dualism here, for the soft sore is nothing but a poor degraded, bastard, and unprolific* child of the one true syphilis.

Perhaps some may be saying that I am asking them to believe a great deal on very little evidence. Candidly, I do not think so; for although I admit I offer nothing that can be called proof, yet the probability seems very strong. At any rate, the theory advanced does appear to offer some explanation of what was before not explained, and it relieves us from the necessity of trying to believe the very unlikely suggestion that two separate specific poisons, each liable to be conveyed chiefly in the venereal act, have existed side by side for many centuries without becoming intermixed.

Let us next try how this theory will fit with what we observe in practice.

We have first the fact, which is universally acknowledged, that the soft sore has no period of incubation. This is precisely what we should expect on the theory of pus-contagion, and precisely what we should not expect if there were any specific virus in the case. It is parallel with what happens in gonorrhœa, in purulent ophthalmia, in porrigo of the skin, and, as I believe, in erysipelas. Next we have the frequent multiplicity of soft sores, which is to be explained by the fact that the purulent secretion from the first is contagious. It may happen that several parts have been inoculated simultaneously from the first contagion, but it is probable that in most cases the first sore stands in the position of parent to the others. You may sometimes see a dozen soft sores on the same penis, and not unfrequently some spots covered with pus-scabs (porrigo) are seen on the patient's thighs and abdomen. The ease with which you can inoculate the soft sore on any part of its possessor's skin, and for any number of times, is simply another illustration of the same fact. The pus which easily effects accidental contagion is of course easily inoculable; and, inasmuch as there is no specificity in the matter, nothing but a purely local process, the constitution never becomes protected, however many times it is repeated. I must claim also the circumstance that soft chancres may differ one from another within very wide limits of variability as another argument in support of my view. I believe it is generally acknowledged that when a soft chancre is transmitted by inoculation the second sore very closely resembles its parent; and I am far from wishing to assert that in the matter of contagion all pus is exactly alike. Indeed I have already said that it is modified by the special kind of tissue from which it is produced, also by the stage of the inflammatory process, and, allow me now to add, by the special type of the inflammation. By the term "type" I mean the whole of the clinical peculiarities which the inflammatory process in question shows: thus we may have a phagedænic type, a suppurative type, an erysipelatous type, a diphtheritic type, and many others. The word "variety" would perhaps be equally applicable; but, whichever word we use, I wish clearly to say that in speaking of a type of inflammation it is intended to imply only clinical peculiarities, and not specificity. Just in the same way we speak of a greyhound, a pointer, or a spaniel, meaning in each case to denote a well-recognised type of dog, but by no means to imply specific distinctness. All dogs will of course breed together, and their mongrel progeny may exhibit all varieties of mixed qualities. It is practicable of course, with care, to secure what are called "pure breeds"; and my suggestion is that a precisely analogous law obtains in reference to pus-contagion—the progeny will resemble its parent. Thus, I think, I am quite entitled to recognise the peculiarities which soft chancres present, their similarity one to another, and the considerable degrees of dissimilarity from sores which result from other causes, without for a moment acknowledging that these facts imply true specificity in origin. It is simply a matter of degree; and it is highly probable that you may breed up, so to speak, a certain quality of pus until, so long as due precautions are taken, it will manifest almost invariably peculiarities in its products which are deceptively like those of a species.

You will all be aware that it is extremely rare for any surgeon, however well skilled he may suppose himself in the diagnosis of the results of venereal disease, to recognise a soft chancre on any other part than the genitals. It is for the most part on these surfaces only that soft sores will assume peculiarities which are easy of recognition. If a chancre is diagnosed on any other part, that chancre is always an indurated, or at any rate an infecting one. Yet there can be little doubt that persons do, not unfrequently, get contaminated with the pus-secretion from non-specific venereal sores on other parts than the genitals. The product, however, has not enough of peculiarity to lead to its recognition. The precautions necessary for breeding "true" have not been observed. The conditions indicative of peculiarity of type fade away, and we recognise only an irritable pus-secreting sore, to which we may give, according to our habits and nomenclature, the name of impetigo, porrigo, or ecthyma.

(*To be concluded.*)

NOTE OF A NEW FORM OF PSEUDO-PARAPLEGIA.

BY T. GRAINGER STEWART, M.D., F.R.C.P.,

PHYSICIAN TO THE ROYAL INFIRMARY, LECTURER ON CLINICAL MEDICINE AND ON THE PRACTICE OF PHYSIC, EDINBURGH.

T. S——, aged thirty-five, a labourer, married, a native of and resident in Fife, was admitted to the Royal Infirmary, under my care, on July 23rd, 1875, complaining of want of power in both legs and the right arm, from which he has suffered more or less for three years. He states that he has always been healthy, and never met with any accident. At the age of twenty-two he went to New Zealand, and remained there for ten years. From the age of twenty-five to twenty-seven he was occasionally guilty of masturbation. He enjoyed perfect health till he was on his homeward voyage, when he felt a pain as of something tied tightly round his waist. This pain prevented him from standing upright, and he sometimes felt that he dragged his right foot slightly. On reaching home he suffered from a stiffness in his legs, and dizziness, with occasionally a peculiar sensation which he describes as an uneasiness passing up the left leg, then down the right, becoming in the latter part of its course as if boiling water were scalding the limb. He consulted various practitioners, one of whom applied the cautery over the spine with decided benefit. In January, 1873, he married. He did not indulge excessively in sexual intercourse, but he observed that the completion of the act appeared to be delayed. He worked as a labourer and was frequently employed in carrying bags, and was able to continue at his occupation until nine months ago, when the stiffness of his limbs had so increased that he had to give up the attempt. His habits as to food and drink have been favourable; his home has always been comfortable; his work pretty hard, but not excessive. He knows of no nervous disease in his family.

On admission he was sound in all respects except the nervous and muscular systems. He had no abnormal sensation except slight numbness in the fingers of the right hand, especially the thumb and forefinger; sensibility to all kinds of impressions natural everywhere, except in the right hand, where it seems slightly diminished. His sight has failed a little of late, especially in the right eye. His pupils are sluggish, of medium size and equal. In the right eye the disc is greyish, its outline ill defined, and the vessels are diminished in calibre. The left eye is similarly but less affected. Hearing, taste, and smell are natural. The muscular sense, as tested by weights, and by standing and walking with the eyes closed, is natural. The natural reflex actions are normally performed, except that micturition is often slow and the bowels are singularly constipated. On tickling the soles the legs do not jerk, but become rigid from general spasm of the muscles. Voluntary motion is normal in the head, thorax, abdomen, and left arm. The muscles of the right shoulder and upper arm are normal, and he can grasp firmly with the hand, but he says he feels it somewhat weak, and incapable of finer movements, such as buttoning. When he attempts prolonged finer movements, as in writing, his efforts are from the first slow and unsatisfactory, and soon fail altogether, not from any jerking, but from failure of the action of his fingers. The movements of his legs are singularly impaired. He can flex the thigh quite well, but he cannot, when lying in bed either on his face or his back, bend the knees nor the ankles nor the toes. As soon as he attempts to do so the flexor muscles come into play, but at the same moment the antagonistic muscles contract correspondingly, and the limb becomes rigid. He has learned, by moving his pelvis and hip-joints, to obtain some mechanical advantage, and get his flexors to prevail, so that in a roundabout way he obtains flexion; but this is both slow and unsatisfactory. As soon as he ceases to aim at flexion all the muscles relax. When he stands he plants his feet somewhat apart, but is quite steady; and closing his eyes makes no difference. His legs are quite rigid, all the muscles being contracted, and the right foot slightly inverted. When he tries to walk, the legs continue rigid; there is no jerking; throwing himself over on the supporting leg, he brings the foot round with a swing, scarcely clearing the ground, and he moves it slowly; the moving leg looks as if it were powerful, but held down and back by a heavy weight. His legs are easily fatigued, and he likes to help himself forward by grasping objects with his hands. He has, owing to the rigidity of his limbs when he attempts to move, the greatest difficulty in going up or down stairs. He manages to sit down by making use of the weight of his body, throwing the centre of gravity behind the line of his legs, and he is able to rise without much difficulty. Getting into bed is a difficult process on account of the rigidity of the limbs. He throws himself diagonally into the bed, his pelvis resting on the edge, and then he swings his legs round into the bed. The vaso-motor and nutritive functions are normal, as are also the cerebral and mental. The cranium and spine are well formed. Percussion over the lumbar region elicits complaint of some degree of tenderness. The hot sponge brings out nothing peculiar. The bones and joints are normal. The muscles are in all parts well nourished. In both legs, also apparently in the right hand, voluntary effort at movement or peripheral irritation induces spasmodic contraction of all the muscles, so that the limb becomes rigid, as above described. There is no tendency to cramp. After prolonged exertion jerking of the muscles is noticed, but it soon passes off. There are no fibrillary twitchings. Electro-sensibility and electro-contractility are normal.

---

* "Unprolific" in the sense of not being able to produce a blood disease; prolific enough as to its capability of causing local contagion.

The peculiar features of this case are, the almost perfect soundness of the sensory functions, and the undue excitability of the motor structures, whereby voluntary movement is prevented by corresponding and equivalent contraction of the antagonistic muscles, general contraction being also induced by peripheral irritation.

These features do not correspond to anything which is described in the works on diseases of the nervous system to which I have access. It is sufficiently clear that, although the patient is practically paraplegic, he is not really so, seeing that the power of muscular contraction is impaired in no part of the lower limbs. It is therefore among the pseudo-paraplegias that we must look for analogous cases. In M. Jaccoud's classical work, "Les Paraplegies et l'Ataxie du Mouvement," there are described five forms of pseudo-paraplegia, viz.:—

1. A result of general asthenia, which is essentially characterised by the debility being as marked in the arms as in the legs, and by all normal movements being performed, although feebly.

2. A result of partial paralysis—that is, of paralysis of individual muscles or groups of muscles.

3. A result of exaggerated spinal excitability. In this form walking is embarrassed or rendered impossible, because contact of the sole of the foot with the ground induces more or less violent reflex movements; it may be either in the extensors or the flexors. This, of course, induces singular jerkings, which interfere with progression. When fully developed it cannot be confounded with paraplegia, because the limb is agitated by movements, sometimes painful, each time that the foot touches the ground; but when it is present in a less degree error is possible, walking being simply rendered difficult or irregular by the sudden contraction of a group of muscles, which interferes with the series of movements necessary for normal progression. If one watches closely, however, the nature and cause of the interference with walking are evident. If the mode of walking does not clear up the case, directing the patient to move in bed infallibly does so; for the movements of the leg are perfectly normal so long as the foot is not touching the ground. This was described by M. Goupil as a form of hysterical paraplegia. The embarrassment of movement is solely connected with reflex irritation; voluntary motion is perfectly intact. And the embarrassment is not merely due to plantar hyperæsthesia. That hyperæsthesia exists in some cases, but not in all; and it is generally quite evident that it is the excitability of the cord which is at fault; the excito-motor elements have become excessively sensitive.

4. A result of plantar anæsthesia. The gait is hesitating and unsteady.

5. A result of locomotor ataxia, due to sclerosis of the posterior columns of the cord.

It is obvious that our case cannot be referred to any of the first four categories, and a little consideration should satisfy anyone that it is not referable to the fifth. The three great essential features of locomotor ataxia are wanting. The patient can stand and walk almost as well with his eyes shut as open; his walk is slow and stiff, not jerking, and is unaccompanied by the characteristic stroke of the heel on the ground; he is as helpless in bed as out of it; and the sensory functions are unimpaired.

What, then, is the nature of the affection? It certainly is not merely hysterical, or of the functional character which in women we are accustomed to designate by that title, for it is not attended by any of the ordinary symptoms of that malady, and the early history of the case, supported by the organic changes in the eye, afford conclusive proof that organic disease of the cord exists.

What columns are affected? Certainly not the posterior; for the sensory functions are normal. Certainly not the grey matter to any grave extent; for reflex action, electro-contractility, and the nutrition of the muscles are unimpaired. With equal certainty we may say that the antero-lateral columns are affected, as is proved by the abnormal motor excitability. That the peculiar action is of spinal, not of cerebral, origin is proved by its occurrence in answer to irritation of the soles as well as on voluntary effort.

What is the nature of the lesion? The origin and progress of the case, taken with the affection of the optic nerve, forbid the idea of its being merely functional; and yet it may be hoped that the organic lesion does not extend deeply into the substance of the cord. The commencement during a long voyage, the feeling as of a tight cord round the waist, the giddiness, and the uneasy sensation in the limbs, render it highly probable that a degree of myelitis then existed. The gradual progress towards rigidity on exertion renders it likely that a degree of sclerosis exists. Still, as it is three years since the illness commenced, and as there is even now no true paralysis, or almost none, in the legs, there seems to be reason to hope that the symptoms may be in great measure due to increased excitability of a functional nature.

The condition which appears to me to be most closely allied to what occurs in the case is that which is known as associated movements (Mitbewegungen). Referring to this, Leyden* says that its essential characteristic is that when it is intended to bring a voluntary muscle into play, simultaneous contractions occur in other groups. It is seen in the healthy condition when violent effort is made. Nothnagel regards it as a result of an irradiation of the voluntary impulse. He remarks that the more intense that impulse is, the more widely is its irradiation diffused. Sometimes, in morbid conditions, the intended movement is weakly performed, the other strongly, so that a result the opposite of what was intended is obtained. In cases of paralysis of the extensors of the forearm, for example, the patient may produce flexion when he purposes to extend the fingers. In pareses of the legs it is observed that the associated movements become stronger at every step as the voluntary effort to walk increases. Careful observation of the case under consideration shows that it does not exactly correspond to this in respect that there is, so far as I can make out, no paralysis, only the abnormal irradiation of the voluntary impulse.

A question of great importance is, whether the irradiation in our case is due to irritation originating in sclerosis of the cord. It is quite possible that it may be; and if so, we may expect to find a further gradual extension of the disease, with increase and alteration of the symptoms, true paralysis becoming ultimately developed.

---

* Klinik der Rückenmarks Krankheiten, vol. i., p. 133.

Meanwhile it is clear that the object to be kept in view in treatment is the diminution of the excitability of the spinal cord. The application of icebags along the spine appears to be invariably followed by temporary improvement. When they have been applied for some time, the patient bends his legs quite readily; but when he attempts to walk, little difference is noticed. Ergot of rye has failed to do good; conium has also failed; chloral hydrate appeared to prove in some degree beneficial, but latterly has been found to be of little use. Other remedies must be tried, in the hope that the irritability may be overcome.

Charlotte-square, Edinburgh.

REPORT OF

A CASE OF FEMORAL ANEURISM.

BY FLEET-SURGEON JOHN ELLIOTT, R.N.

(*Communicated by the* DIRECTOR-GENERAL OF THE MEDICAL DEPARTMENT OF THE NAVY.)

S. T——, gunner, Royal Marine Artillery, aged thirty-seven, single, of spare habit, thin, sallow features, and prematurely-aged appearance, was admitted into the Naval Sick Quarters at Halifax on the 6th of June, 1874. During eighteen years' service he has been in the hospital with intermittent fever, pneumonia, syphilis (not constitutional), and bubo. Otherwise he has enjoyed good health, occasionally, however, complaining for days at a time of a stitch beneath the left nipple. He is of temperate habits, and does not smoke. For the last two years and a half he has been employed as coachman to an officer on this station. The patient stated that on Saturday, the 30th of May, he had a number of heavy packages to lift and place in position, and among them a barrel of vegetables weighing 3 cwt. The following day, though not complaining, he did not go out, and on the Monday "felt curious," finding a great stiffness from the knee to the hip when he got up. These symptoms increased during the day, and prevented his sleeping at night. He felt "as if he had been beaten about the thigh with a stick." On Tuesday morning, when getting out of bed, he noticed a lump, the size of a "hen's egg," in his left groin, beating forcibly. He went about his customary duties, however—washing a carriage, cleaning harness, &c. Towards the evening the limb felt numb, and he applied a turpentine stupe. The following day the numbness had disappeared, though the tumour had increased in size, and the pulsation was stronger. Went about his duties as usual—driving, &c.; and at 11.30 P.M., on his way home, he felt the cold very much. On Thursday there was a continuance of the same signs. On Friday he took to bed; and on Saturday morning, the 6th of June, at 9 A.M., he applied for relief at the Naval Sick Quarters, and was at once admitted.

Present condition.—Upon examination a large tumour, measuring 5 in. (transversely) by 4 in. (vertically), somewhat globular in shape, but compressed on its surface, and pulsating visibly with great force, was found at the upper and anterior part of left thigh, occupying the greater part of Scarpa's space and whole of inguinal region, pushing up Poupart's ligament, and obscuring situation of anterior superior iliac spine externally. Upon palpation it was found distinctly circumscribed, hard, and tense, with greatly thickened coats, and distensile pulsation. Its surface was marked by a cicatrix two inches in length, where a bubo had been opened some time before. A soft bruit was heard all over the tumour, and with greatest distinctness internally over the artery. The heart sounds were found normal, though somewhat deficient in strength, and the general health was good.

General record.—Patient was at once placed in bed, and ordered a mixture containing two scruples of tincture of digitalis and one grain of tartar emetic, one-eighth part three times daily; low diet with milk. Digital compression was applied for two hours over external iliac artery, in close vicinity of tumour, and had the effect of almost stopping the pulsation, the bruit disappearing; but the size of the tumour was not lessened, nor could it by pressure be emptied of its contents. Patient complained greatly of numbness of thigh below seat of aneurism during and after its application, and the temperature of the leg and thigh of the affected side was found lower than that of the other. The artery was again compressed for an hour at 2.30 P.M., but had to be stopped on account of the pain to which it gave rise. It was again attempted at 4 P.M., but could not be borne. The pulsation in tumour is stronger—85. Ice was applied at 6 P.M., and at 8 P.M. it had lessened somewhat.

June 7th.—Digital compression was tried, but could not be borne. Slept three hours last night. Complains of numbness of left leg, and hot-water tins were placed around it. Measurement round left thigh over tumour, 22 inches. At 8 P.M. complained of numbness of limb. Stop ice. Temperature in flexure of left knee, 97·4° F.; right ditto, 96°. Ordered one ounce of castor oil, as bowels were confined.

8th.—Tumour measures 6 in. (transversely) by 4 in. (vertically); left thigh around tumour, 23⅛ in.; measurement round upper right thigh, 20 in. There has been an increase of one inch in a transverse direction. No numbness in thigh; slept well; bowels have acted freely. Temperature in left flexure of knee, 95 2°; right ditto, 95·4°. Ordered the following mixture:—Tannic acid, two drachms; tincture of digitalis, half a drachm; to eight ounces of water; one ounce every hour. Pulsation in tumour, strong distensile, 89. The thigh was flexed on the abdomen, and bandaged in that position for about four hours, when the limb was straightened, patient complaining of the constrained position. At 4.5 limb again flexed on abdomen, till 8.30, when numbness and pain shooting down inside of thigh, with heat of parts coming on, it was stopped. Temperature of right flexure of knee, 97·2°; left ditto, 98·1°. Bowels moved twice to-day.

9th.—Slept well; pulse 80; tumour measures 3¼ in. vertically, 6 in. transversely; temperature of right flexure of knee, 96 3°, left ditto, 97·3°; pulsation quieter; complains of numbness down the centre of the thigh; temperature near tumour, 98°. By means of a tourniquet kept in position by relays of nurses, pressure was kept up for three hours and a half, the circulation through tumour being lessened considerably. It was again applied from 9 till 10 P.M.

10th.—Slept from 9 till 2 A.M. Temperature of right leg 98·1°; of left, 96·4°. Tumour measures 6⅛ in. transversely, 4¼ in. vertically. Measurement around thigh 26 in. Pulsation in tumour 90. Pulsation can be felt in both tibials to-day for the first time; there is a slight difference in the pulsations. Surface of skin over tumour slightly discoloured and finely rugated. Bruit heard over whole surface. Tumour more compressible than it was. At intervals pressure was kept up, as during yesterday. At 4.15 Carte's tourniquet was placed in position and the pad screwed down till pulsation or bruit could not be detected in the tumour. It had to be removed on account of faintness and palpitation of heart, which attacked the patient shortly after its application. Great distress continued for the rest of the day. A morphia draught was given at night.

11th.—Has passed a good night. The tumour has increased in size, measuring 6½ in. transversely and 4½ in. vertically. The skin covering it is livid and discoloured, and corrugated. To the touch it is softer at its most prominent part. The pulsation has increased in strength. Temperature of right flexure of knee, 96·4°; of left ditto, 98·1°. Pulsation apparent in posterior tibial artery of right side. Bruit loud all over the tumour; most distinct internally. At 9 A.M. patient was given a dose of castor oil. At 10 o'clock, as the bowels had not acted, a simple enema was administered, a small quantity of fæces coming away.

A consultation was held with the medical officers of the ship, Dr. Jennings of the Halifax Civil Hospital, and Dr. Douglas, Army Medical Staff; and it was decided to tie the external iliac, or, if impracticable, the common iliac artery.

Operation.—Chloroform was administered, and at 12.15, patient being well under its influence, I made an incision five inches in length, extending from a little inside and two fingers' breadth above Poupart's ligament, at its centre, upwards and outwards, to within three fingers' breadth of the crest of the ilium; and the skin, superficial fascia, external oblique, internal oblique, and transversalis muscles having been divided, the transversalis fascia was exposed, and carefully divided on a director to the full extent of the external wound; the peritoneum was then loosened from the surrounding cellular tissue and drawn up towards the mesial line of the abdomen, and the sheath of the vessels exposed. This having been worked through gently, the ligature (a twisted hempen one) was passed from within outwards, and tied, pulsation at once ceasing in the sac and in the vessel beneath it. Four small vessels required ligature during the operation. The parts through which the incisions were made were found greatly congested from pressure, but the artery appeared to be healthy. The wound was sponged with carbolic-acid lotion, and its edges brought together by seven points of interrupted suture (silver wire); carbolic dressing was then applied with a slight compress and bandage. The whole of the left limb was then enveloped in cotton wool with a flannel bandage and surrounded by warm-water tins. Pulse 92. No change in tumour. At 1.30 one drachm of solution of morphia was given, and again at 3. At 4 o'clock he complained of numbness of the left leg. Pulse 94. Slept for two hours towards evening. He was ordered one grain of opium pill every fourth hour. Pulse 100. At 10 P.M. comfortable; no pain; leg warm; pulse 100; passed urine. At 11 P.M. was sleeping.

June 12th.—9.30 A.M.: Passed a good night; pulse 95; temperature in axilla 101·4°; thirsty; restless. Abdomen distended and tympanitic. Slight oozing from wound, staining bandages. Complains of numbness of left foot; and on examination this is found to be very cold. Tins of hot water renewed. To continue the opium pill. Has taken nothing but a little milk-and-water since the operation.—12 A.M.: Sleeping.—1 P.M.: Has passed water; no pain; pulse full, 102.—5 P.M.: Pulse 124; temperature 101·4°; respiration 24. Temperature of left leg (hot-water bottles in vicinity) 96·4°.—6 P.M.: Pulse 130, small, soft, and compressible; temperature 102·4°; restless; tongue white, parched; great thirst; eyes bright, suffused; skin dry and rough. When seen at night he was perspiring a little. Had passed urine involuntarily at times in bed during the day; but before visit had passed a vesselful without difficulty. Complains greatly of flatulence.

13th.—Did not sleep last night. Pulse 124, soft, small, compressible; tongue white and parched; restless, throwing off clothes. Suffers greatly from tympanites. Temperature in axilla 99·2°; in vicinity of tumour 100·1°. Tumour measures 5·2 in. transversely, 3·4 in. vertically, and feels harder. No evidence of returning pulsation. Temperature of left leg 95·3°; of right do. 94·3°. Was ordered ice to relieve thirst, and beef-tea during the day. Abdomen distended, tympanitic, and painful on pressure. Not much discharge from wound. Tumour hard and tense. Left leg and foot warm. Has been taking opium pills during the day, but has only slept two hours since 11 o'clock last night. Ordered one drachm of solution of muriate of morphia; to be repeated if he does not sleep.

14th.—7 A.M.: Slept for two hours last night, the rest of the time dozing. Pulse 135; skin warm; left leg and toes warm. Upon removing the dressings, which were slightly stained with discharges, the wound was found looking healthy, and united for part of its extent. At its lower angle, where the ligature came through, there was a slight sanious discharge. The wound was redressed, and soiled linen removed. The abdomen continues distended and tympanitic. Got nourishment in small quantities at repeated intervals during the day, and continued taking the opium pills. Ice was also given at intervals. The bowels have not acted since the operation. The wound discharged more freely after redressing. At 9 P.M. the patient was found very restless; the pulse 142; tongue thickly furred; vomited a little during the afternoon; is slightly delirious. 11 P.M.: Sleeping.

15th.—Awoke at 8 A.M. covered with a cold clammy sweat; extremities cold; pulse 72, irregular; countenance anxious; passed urine in bed; conscious. Stimulants were at once administered, and hot-water tins renewed around extremities.—10 A.M.: Had rallied a little. Was given brandy, egg-mixture, and beef-tea at short intervals. A large piece of spongio-piline, wrung out of hot water, was kept constantly applied to the abdomen. Passed about a pint of dark-coloured turbid urine. At 12 A.M. his pulse was 150, small, soft, and compressible. Pain on pressure over the abdomen. Wandering slightly; perspiring. At 1.30 there was nausea and slight vomiting. Brandy was administered, and a draught containing half a grain of muriate of morphia.—4 P.M.: Slept a little since last visit. Gradually sinking. A marked change for the worse since last visit. Pulse rapid, fluttering; cannot be counted; talking incoherently; floccitatio.—5 P.M.: Pulse 199, fluttering; cold clammy sweat over the body. Floccitatio continues. Sighing respiration.—7.15: Sinking rapidly; rapid fluttering pulse. Stimulants continued at short intervals. Unconscious.—8.45: Expired.

Autopsy (performed twenty-four hours after death).—Rigor mortis absent; body emaciated; abdomen distended and tympanitic; scrotum dark and congested. A tumour, soft on palpation, 5·2 in. transversely, 3½ in. vertically, is situated in left groin and Scarpa's space. About 2 in. above it is a wound 5½ in. in length, extending outwards from the centre of Poupart's ligament, and almost united in the intervals between seven points of silver suture. Lungs healthy; old adhesions connecting lungs and pleura on both sides. About two ounces of clear yellow serum in cavity of pericardium. Heart small; flaccid; more than the normal deposit of fat in interventricular furrows; slight warty vegetations on anterior segment of mitral valve; slight roughening on anterior surface of ascending aorta; decolorised coagulum in right auricle; dark clot in pulmonary artery. The intestines were found distended with gas; a portion of the left lower edge of the omentum, four inches in extent, was congested, adherent to intestine beneath; lymph was effused on its surface. Liver, spleen, and kidneys healthy. A piece of the lower part of the ileum, six inches long, was intensely congested; the cæcum below it contained an accumulation of hardened fæces; about four inches of the colon at the sigmoid flexure was also found congested, the rectum below containing some hardened fæces. Gall bladder distended with bile, dark externally. The intestines were removed; the surgical wound in abdominal walls was found united superficially almost throughout the whole extent. More deeply, however, such was not the case, the muscles, &c., in the line of incision being congested and disorganised. Pus, green in colour, extended upwards for some distance on abdominal walls, between planes of muscles. Upon raising the peritoneal sac from the iliac fossa, diffuse cellular inflammation was found extending upwards as far as left kidney. The pus in the iliac fossa was of a pink tinge. The surgical wound was two inches above and parallel to Poupart's ligament. Upon removing the integument and superficial fascia from the front of the left thigh, the aneurismal tumour, tightly bound down by the sartorius muscle and the fascia lata, was discovered. Upon cutting across the former the tumour assumed a more conical shape. Its most prominent part was found greatly thinned, the same condition existing externally. It was with difficulty dissected out of its bed in the psoas, iliacus, and pectineus muscles, a considerable portion of these, together with a part of the capsular ligament of the hip-joint, having to be removed on account of their connexion with the tumour. Some doubt existed as to whether a depression observed on the head of the femur, below the acetabulum, was not due to pressure of the tumour, but on account of the history of the short duration of the disease, it was decided not. A few nerves were found stretched across its surface. The aneurism was formed on the external side of the femoral artery, from which it extended outwards, probably due to rupture of its internal and middle coats—its external coat, together with the sheath of the vessels, which was found greatly thickened, forming the coverings. The measurements were 3½ in. vertically and horizontally, 9 in. round greatest circumference. Its contents were fluid, a considerable portion of them (dark blood) having escaped by accidental rupture. The ligature was found firmly applied on the external iliac artery, two inches above the tumour, and two inches below the origin of the internal iliac artery. The femoral artery was involved for an inch and a half in the formation of the tumour; it appeared healthy. The femoral vein was found adherent, especially at the centre; above this its coats were thinned and dilated; below, greatly thickened (six lines). A quarter of an inch below the emergence of the femoral artery from the tumour two arteries were given off—the profunda femoris, hard and nodulated to the touch, and the external circumflex ilii.

The walls of the tumour were excessively thinned throughout, more particularly above and externally. The muscles in immediate contact were softened and disorganised.

Remarks.—The cause of the fatal termination in this case was diffuse cellular inflammation. Owing to the large size of the tumour, the parts around were subjected to considerable pressure, causing congestion &c., and were unable to regain their vitality after the operation.

NOTE ON

THE TREATMENT OF SCARLET FEVER BY THE EXTERNAL APPLICATION OF COLD WATER.

WITH TWO CASES.

By JOHN EDWIN EDDISON, M.D.,
PHYSICIAN TO THE LEEDS INFIRMARY, THE FEVER HOSPITAL, ETC.

(*The Cases reported by* Dr. Steell, *Resident Medical Officer at the Fever Hospital.*)

(*Concluded from page* 341.)

Case 1.—S. F——, aged eight, was admitted into the Leeds Fever Hospital on the morning of the 13th of May, 1875, being the third day of illness. On admission, the following notes were made:—"Face congested and of a dusky hue. A nearly uniform blush of redness is observable over the upper part of the chest anteriorly, and upon the hands there is a faint but characteristic scarlatinal rash; elsewhere there is no rash. Temperature in the axilla 104·2° F. The skin is dry, and feels extremely hot; tongue thickly furred, red at the tip and margin; fauces and tonsils much congested and swollen; diffuse, partly œdematous, swelling at the angles of the jaw, accompanied by pain and tenderness. Over the lungs, posteriorly and inferiorly, a few coarse bronchitic rhonchi; elsewhere a vesicular murmur. Respiration 24 per minute; action of heart excited; pulse 144; heart-sounds clear. Patient is very drowsy, and her breathing heavy. Urine contains no albumen; sp. gr. 1020." She was ordered a tepid pack, two sheets, each applied for ten minutes. When taken out the temperature had fallen to 101·8°. This was at noon. At 1 P.M. it had again risen, and reached 105·3°. Another pack was immediately ordered, cold instead of tepid water being used. After thirty minutes, three sheets having been applied one after another, her temperature had again fallen, this time to 100°. A fourth and fifth sheet were applied however, but, on her being placed in the latter, slight shivering with chattering of the teeth supervened; when taken out and dried the temperature was found to have risen to 102°. The patient was now slightly delirious, and still very drowsy. At 5 P.M. the temperature was 105°; pulse 144, and weak. Powerful grinding movements of the lower jaw have supervened. She was now placed in a tepid bath, the water of which was gradually cooled down. During the bath she appeared more sensible, but the grinding movements of the jaw continued. Temperature, when taken out, 99°. She was kept in thirty minutes. The pulse was scarcely perceptible; but this seemed due chiefly to a local contraction of the arterial coats, as the action of the heart was ascertained by palpation and auscultation to be still vigorous. At 7 P.M. the temperature was 101·6°; at 7.30, 103°; at 8, 103·2°. A patch of deep-coloured rash was now observable on and above the elbows. At 10 P.M. the rash was well out on the arms and forearms. It was of a deep colour, and coarsely mottled in aspect. The patient was very drowsy, and slept with the eyelids open. Pupils normal; temperature 105°. At 11 P.M. she was again placed in a tepid bath, which was cooled down as before. During this bath the rash upon the arms became intense. The patient talked rationally while immersed, but occasionally rambled. Grinding movements of the jaw reappeared. She was kept immersed for forty-five minutes, and when taken out was much less drowsy, while her temperature had fallen to 95·6°. Half an hour after the bath it had risen one degree. The treatment adopted, besides bathing, consisted in the application of cold compresses to the throat, 3 oz. of wine in the twenty-four hours, and nourishment in the form of strong beef-tea and milk. The throat was also sponged with Condy's fluid.

May 14th (fourth day of disease).—Temperature during the night: 1 A.M., 101°; 2, 103·2°; 3, 104·2°; 4, 104·2°; 5, 104·6°; 6, 103·4°; 7, 104·2°; 8, 103·8°; 9, 103·6°; 10, 104·6°. Pulse 148. After last night's bath she slept quietly for three hours, and then woke up asking for a drink. This morning she continues very drowsy, her breathing heavy and snoring. Rash well out on the arms, but not so brilliant as during the bath. Taking nourishment well. Tongue red and characteristic of the disease. Passing urine in bed. Bowels open.—2.30 P.M.: Rash brilliant on arms; well out on legs and thighs. Temperature has stood persistently at a few points above 104°.—4.30 P.M.: Temperature 104·4°. Placed in the bath again. The temperature in ten minutes had fallen to 101°, in twenty minutes to 99·6°, and in thirty-five minutes to 95·5°, when she was taken out.—At 5.30 P.M. the temperature was 96°, and at 6.30, 101·6°.—7 P.M.: Pulse 136; sleeping quietly. During the last bath she was quite conscious and talked a good deal.—10.30 P.M.: Rash intense on arms; over the trunk a distinct mottling. Temperature 104·4°. Placed in bath; kept in fifty minutes. Temperature when taken out 96·2°.

15th (fifth day of disease).—Temperature during the night: at 12.45 A.M., 101·4°; 1.30, 102·2°; 2.30, 104°. At 2.30 she was placed in a wet pack, and the temperature at 3 A.M. had fallen to 101°.* At 4 A.M. it had risen to 103·4°. At 6 she was again placed in a pack, the temperature at 6.30 having again fallen to 101°. Pack continued, sheets changed every ten minutes, and cold water used. At 7 the temperature was 102·2°; and at 8 it was 102·8°, in spite of pack. She was then taken out. Temperature at 9 A.M., 103·2°; at 10, 103·8°. Rash universal; intense on extremities, resembling erysipelas. Tongue red, and as yesterday. Bowels open twice. Pulse 144. Patient is more intelligent and much less drowsy. At 11 A.M. the temperature was 104°, and at 12 noon 105°. The patient was again ordered a cold wet pack, which proved unsuccessful at first; but by placing her, wrapped in a sheet, in an empty bath, and sponging her with cold water, the temperature was at last reduced to 98·4° (at 2 P.M.) At 3 P.M. the temperature was 98·4° and the pulse 128, the heart-sounds being clear and its action less tumultuous. At 3.30 the temperature was 99°, at 4.30 it was 102·4°, and at 5.45 P.M. 103·4°. In ten minutes after being placed in a bath the temperature fell to 98°; she was kept in, however, for five-and-twenty minutes. At 7.30 the temperature had risen to 100·4°, and at 10.30 to 103·6°. At 10.45 the patient was delirious, talking of school, &c. Temperature 104°. Drowsy again. Pulse 144. Breathing heavy; respiration 26 per minute. The patient was placed in a bath, with the water at 90° cooled down to 68°. She was kept in forty-three minutes. During the bath the pulse was 128 and the respiration 26. Mind quite clear after the bath. The thermometer could not be got to register higher than 95° in the axilla.

16th.—Temperature at 1 A.M. 99·8°; at 4, 103·2°. On being placed in a bath, the temperature was reduced in fifteen minutes to 101·4°, in thirty minutes to 96·4°, and in forty-five minutes to 96·2°, when she was taken out. At 6 A.M. the temperature was 98°; at 10, 102·6°. Was sick in the last bath. Patient usually drinks freely of milk or beef-tea before entering and during the bath. Respiration 28 per minute; pulse 144; tongue dry and glazed; bowels not moved; passes urine in bed; takes food pretty well; breath fetid. At 12.30 P.M. the temperature was 103·4°. In ten minutes after being placed in the bath the temperature had fallen to 99·8°, and in thirty minutes to 95·2°, when she was taken out. At 5.20 P.M. the temperature was 103°. She was placed in the bath at 6 P.M., and in ten minutes the temperature had fallen to 98·4°, and in thirty minutes to 95·2°, when she was taken out. At 7 P.M. the pulse was 96 (taken with the stethoscope also). The temperature at 10.15 was 101·8°.

17th (seventh day of disease).—Temperature at midnight, 102°; 1 A.M., 102·6°; 2, 102·2°; 3, ditto; 4, 102°; 5, 102·2°; 6, ditto; 7, 101·8°; 8, 102°; 9, 101·4°; 10, 101°. Tongue moist, but clammy; bowels moved thrice; breath very fetid; fauces still congested; tonsils enlarged, white pultaceous matter on left one; glands at the angles of the jaw swollen, but not painful; pulse 128. Throat sponged with Condy's fluid. Temperature at 11 A.M., 102°; 12, 101·8°; 1 P.M., 102°; 2, 102·2°; 3, 102°; 4, 102·6°; 5, 103·3°; 6, 103·6°. Placed in bath at 6.30. In ten minutes the temperature was 98·4°; in twenty-five minutes 95°. Taken out. At 8 P.M., temperature 99°; rash less brilliant.

---

* Duration of pack not noted.

18th.—Temperature at 1 A.M., 102·2°; 2, 103°. At 2.20 placed in bath; temperature reduced in ten minutes to 101°; kept in thirty minutes; when taken out the temperature was 96°; at 3.30 A.M., 98°; 4, 99°; 5, 100·6°; 7, 102°; 10, 102·2°. Pulse 136; tongue dry and glazed; bowels moved twice; desquamation beginning on face. At 12 noon, temperature 102·4°; 2 P.M., 102·8; at 3.55, put in bath, water at 70° F. In ten minutes, temperature 98·4°; in twenty minutes, 98°. At 5 P.M., temperature 98°; pulse 130; respiration 22. The duration of this bath unfortunately was not noted, but it probably was only twenty minutes. Tongue quite moist afterwards. At 6 P.M., temperature 100°; 7 A.M., 101°; 8, 102·6°; pulse 140; heart's impulse feebler.

19th.—12 midnight: temperature 103°; pulse 144. At 12.15 A.M., placed in bath; at 1 A.M., temperature 96° (duration of bath again omitted). When taken out, pulse 94; respiration 32; tongue, which had become dry, again moist. Temperature at 2 A.M., 97·2°; 3, 101°; 4, 101°; 5, 102°; 6, 101·2°; 7, 101°; 8, 101°; 9, 102°; 10, 102·4°. Pulse 124; tongue still dry and glazed.—3.15 P.M.: Temperature 103°; pulse 132.—4.35 P.M.: Placed in bath. In fifteen minutes temperature reduced to 98·4°. Taken out at 5.30 P.M. Pulse 104.—At 7.50 P.M., temperature 101·6°; 8.40, pulse 132; 10, temperature 102°; 11, 102·4° 12, 101° (?).

20th.—Temperature at 1 A.M., 102°; 2 and 3, ditto; 4, 101·4°; 5, 102·2°; 6, 102°; 7, 101°; 8, 101·2°; 9, 101·4°; 10, ditto. Pulse 124; tongue not quite so dry; bowels acted twice; desquamation progressing.—At 2 P.M., temperature 102·2°; 3 P.M., 102·4°. Pulse 132. At 5 P.M., temperature 102·6°. Bath at 5.30 P.M. In ten minutes temperature down to 100°; in twenty minutes, 98·4°. Kept in twenty-five minutes. At 7 P.M., temperature 100·2°; 9, 101·6°. A clear, healthy, vesicular murmur over the lungs; heart sounds normal. At 11.30 P.M. the temperature had again risen, reaching 103°. Placed in bath for thirty-five minutes. Temperature reduced to 95°. Drank brandy-and-milk after coming out. Pulse 88, shows a tendency to intermission; tongue moist.

21st.—Temperature at 2 A.M., 99°; 3, 99·6°; 4, 100·2°; 5, 102°; 6, 100·4° (?); 7, 101·8°; 8, 102°; 10, 102·6°. Pulse 120; tongue moist; says she feels better; bowels acted twice.—Temperature at 1 P.M., 101·8°; 2.30, 101·6°; at 3, pulse 120; 8.30 P.M., pulse 124; temperature 101·4°; 11 P.M., sleeping quietly; pulse 112; respiration 28; temperature 101·4°; 12, ditto.

22nd (twelfth day of disease).—Temperature at 1 A.M., 101·2°; 2, 101·4°; 3, ditto; 5 and 6, ditto; 7, 101·2°; 8, ditto; 9, 101·4°. Pulse 120, better in strength. Tongue moist; copious desquamation. Temperature at 12 noon, 101·6°; 1.30, 101·2°; 3, ditto; 4, 101°; 5 and 6, 101·6°; 7, 101·8°; 8, 102°. Pulse 120. At midnight sleeping quietly; pulse 108.

23rd.—Temperature during the night: 1 A.M., 100·6°; 2, ditto; 4, 100·2°; 7.30, 100°. At 10 A.M., 100°; pulse 112; tongue clean. Temperature at 8.30 P.M., 102·6°; pulse 120; temperature at 11.45, 102°.

24th.—Temperature at 1 A.M., 101·2°; 2, ditto; 3, 101°; 4, 100·2°; 5, 100·1°; 6, 99°; 7, 99·4°; 8.30, 99·8°. Pulse 108; tongue clean; bowels acted once; no albumen in urine. Temperature at 3 P.M., 100°; 5, 101·6°; 8.30, 102°; pulse 116. At 10.20 P.M. was put in tepid bath; kept in forty minutes; in the first ten minutes the temperature fell to 99·8°, in the second to 99°, and in the third to 98·2°. Temperature at 12 midnight, 99°; pulse 98; sleeping quietly.

25th.—Temperature during the night: 1 A.M., 100°; 2, 100·2°; 3, ditto; 4, 100·4°; 5 and 6, ditto; 7, 100°; 8, 99·6°; 10 A.M., 100°. Pulse 112; bowels moved once; urine contains no albumen. Temperature at 1 P.M., 101·4°; 2, 100·6°; 3, 100°; 4, ditto; 5, 101°; 6, 101°. Temperature at 10.25, 100·4°; pulse 108.

26th.—Temperature at 1 A.M., 100°; 2, ditto; 3, 99°; 4, ditto; 5, 99·4°; 6, 99·2°; 7, 99°; 8, 99·8°; ditto till 10 A.M. Pulse 100. Temperature at 11 and 12, 99·8°; 1, 99·9°; 2, 100·2°; 5, ditto; 6 and 7, ditto; 8, 100·4°; 10.30, 100·2°; 11.30, 101°.

27th (seventeenth day of disease).—Temperature during the night: 1.30 A.M., 100·4°; 2.30, 100·2°; 4, 99·2°; 5, do.; 6, 99·4°; 7, 98·4°; 8, do.; 9, 98·6°; tongue clean; much better in every way. At noon, temperature 99·2°; 2 P.M., 99·4°; 3, 99·6°; 4, 100°; 5, 100·1°; 6, 100·4°; 7, do.; 8, 100·5°; 11.20, 100°.

28th.—Temperature at 2 A.M., 99·8°; 5, 99·2°; 8, 98·6°; 10, 98°; 12 noon, 98·6°; 2 P.M., 99°; 4, 99·4°; 6, 99·6°; 8, 99·2°; 12 midnight, 99·2°.

29th.—Temperature at 4 A.M., 99·2°; 6, do.; 9, 98·4°; 10, do.; 12, 98·6°; 3 P.M., 99°; 6, 99·2°; 10, 99·4°.

30th.—Temperature at 3.30 A.M., 98°; 5, 98·6°; 10.30, 97·8°; 3.30 P.M., 98°; 6, 98·4°; 8, do.

31st.—Temperature at 5 A.M., 98°; 5, 98·2°; 3 P.M., 98°; 8, 99·2°.

June 1st.—Temperature keeps normal; pulse 96.

4th.—Urine normal; no pyrexia.

8th.—Trifling pyrexia has existed for last few nights; 99·8° highest temperature. Slight painful enlargement of the lymphatics at the angles of the jaw is the probable cause.

10th.—Enlarged glands diminishing and have ceased to be painful. Temperature normal; pulse 88 to 96.

14th.—Patient up and well.

17th.—To have fish to dinner; hitherto during convalescence she has had exclusively milk diet. Alcohol was withdrawn as soon as the symptoms of prostration during the worst of the disease had abated. Throughout her illness the ward was kept freely ventilated and the windows frequently open. The urine has been repeatedly examined for albumen, but always with a negative result.

28th.—Dismissed well.

CASE 2.—M. A. F——, aged four, sister to the foregoing patient, was admitted to the Leeds Fever Hospital on the 16th of May, 1875, on the third day of illness. The following notes were made on admission:—"An intense scarlatinal rash covers the whole body. It is of good colour, and in all respects a typical rash. Tongue clean, red, moist, and roughened from enlargement of the papillæ. The fauces and tonsils are considerably congested, but not much swollen. There is some swelling of the lymphatics at the left angle of the jaw. The heart-sounds loud and clear, its action excited; pulse 144; breath-sounds harsh, approaching to the production of rhonchus. Temperature 101·2°; skin feels comparatively cool." The temperature was taken shortly after a warm bath which the patient had on admission, and this no doubt was the cause of the lowered temperature. We have repeatedly had opportunity of making this observation in various febrile diseases, and no temperature taken shortly after a bath is to be considered reliable for diagnostic purposes. No danger of hyperpyrexia seemed threatening, and the temperature was not taken again till the evening, when it was found to have reached 105·3°, while the pulse was 152, so quick as scarcely to be counted. A bath was immediately ordered, the water at first tepid, and to be cooled down subsequently. Placed in bath at 8.30 P.M. In twenty minutes 104°; after thirty minutes' immersion, 101°; in fifty minutes, 98·4°; in sixty minutes, 95·6°. After bath: Pulse 120, intermits occasionally, alters in rate, counted again at 108. Rash livid; some bronchitic sounds over chest. Heart-sounds loud and clear. At 10.45 P.M. the temperature was 98·2°; respiration 24; pulse 136. At 12 midnight the temperature was 100°. Diet to consist of milk only; no medicine or wine; bowels moved twice.

May 17th (fourth day of disease).—Temperature during the night: 1 A.M., 100·6°; 2, 101·2°; 3, 102·4°; 4, 103·2°; 5, 104·2°; 6, 103·2°; 7, 102·4°; 8, 101·8°; 9, 102·5°; 10, 102·4°; 11, 102·8°; 12 noon, 102·6°; 1 P.M., 102·8°. Tongue as yesterday. Bronchitic sounds have entirely disappeared. Pulse 136. At 2.20 P.M. the temperature reached 103·2°. Placed in a bath again, temperature above 70°. In ten minutes it had fallen to 100°; in twenty minutes to 98·4°. When taken out, after forty minutes' immersion, the temperature was 95°. Temperature at 4 P.M., 100°; 5, 100·4°; 6, 100·4°; 7, 100·8°; 12 midnight, 101·5°. Pulse 136. No albumen in urine. Bowels moved once.

18th.—Temperature during the night: 1 A.M., 101·4°; 2, 101·4°; 3, 102°; 4, 101°; 5, 101°; 6, 100·6°; 7, 100·4°; 8, 99°; 9, 99·8°; 10, 100·4°. Pulse 132. Tongue clean and moist. Temperature 12 noon, 100·4°; 7.30 P.M., 102°. Pulse 124.

19th.—Temperature at 2 A.M., 100°; 3, 98°. Evening, 99·2°; pulse 104.

20th.—Sitting up in bed; desquamation on face; rash fading rapidly. Morning temperature, 98·2°; evening, 98·2°. Pulse 108–104. Bowels freely moved.

21st.—Temperature quite normal. Pulse 96.

23rd.—Pulse 84 to 76, somewhat irregular. Temperature quite normal since last report. Cuticle separating in large flakes from hands, &c.

25th.—Playing with toys, and apparently quite well.

27th.—Doubtful trace of albumen in urine.

28th.—No albumen in urine.

31st.—No albumen in urine.

June 3rd.—No albumen in urine.

4th.—Up and well. Milk diet has been continued throughout.

28th.—Dismissed well. Up to to-day the urine has been repeatedly examined for albumen with a negative result.

Leeds.

NOTES OF AN
EXAMINATION OF CAPTAIN WEBB.

By HENRY SMITH, F.R.C.S.,
SURGEON TO KING'S COLLEGE HOSPITAL.

Having had the opportunity of seeing Captain Webb, in the absence of Sir William Fergusson from London, I have made a few notes and observations, the result of the examination of a man who has rendered himself an object of interest to the whole world in general, but in an especial manner to the members of our profession, who are in a better position than any other class of the community to appreciate the wonderful powers of endurance which Captain Webb evinced in the performance of his late most marvellous and unheard-of exploit. I am sorry I had not time to make a more minute examination, and institute some inquiries on other points of interest; but I thought perhaps these few details and observations, imperfect as they are, may be of some interest to the readers of The Lancet.

As Captain Webb, who is 5 ft. 8 in. in height, and weighs 14 stone and a half, stood before me stripped to the waist, I could not fail being struck with the splendid form and symmetry of his chest, neck, and arms, and I was somewhat astonished to find him with such good flesh and so little angularity, as it were, about him. I expected, after such hard training and such severe exertion, that the muscles would stand out in relief and be well marked, as one has seen in prize-fighters and other athletes; but, on the contrary, there was a considerable development of other tissue besides that of muscle. On putting him into various attitudes, however, and making him exert particular muscles, their fine development and power were at once noticeable. The triceps especially, as one would expect, is extraordinarily developed. The scapular muscles and those of the neck are also especially remarkable. I measured his chest, whilst he was standing with his arms held above his head, at two points: first on a level with his nipples, and found that he measured in that situation forty-one inches and a half; around the waist, three inches above the umbilicus, the circumference was thirty-five inches and a half. The arm in circumference, three inches above the elbow, was thirteen inches and a half. The forearm two inches below the elbow measured eleven inches and a quarter. The circumference of the neck on a level with the thyroid cartilage was over fifteen inches.

On examination with the stethoscope I was astonished at the extraordinary volume of air entering the lungs at each inspiration. The sounds of the heart were remarkably clear and healthy.

On questioning him minutely about some points connected with his remarkable feat, Captain Webb gave me some interesting answers. In the first place he very modestly informed me, on my putting to him the question as to whether he could have held together for another mile, that he certainly could not have done so in the state the sea was in at the time. To my question as to whether he felt cold at any time whilst he was in the water, he answered decidedly, No. This, I think, is a point of special interest, for with ordinary persons who have remained in the water for a long time swimming we know that the sensation of cold comes on before that of weariness and exhaustion, and warns the swimmer to get on to his native element. A striking illustration of this fact occurred to my observation only last week in a young gentleman who, wishing to emulate Captain Webb's feat in a small degree, swam an immense distance in the sea by the side of a boat. He informed me that he was prompted to give up because he felt chilly, not because he was tired.

To my question about the porpoise grease with which his body was anointed, Captain Webb informed me that he did not know that it helped him at all—in fact, that he rather thought he did not derive any benefit from its use. However, of course this point could only be settled by the direct experience of a swimmer performing a feat under exactly similar conditions both with and without the oil.

On putting the question as to whether he suffered from any difficulty in breathing during his passage, he said, "Not at all, with the exception of that produced now and then by the mechanical force of the waves dashing against my mouth and nose"; to avoid this he had to keep his head well back, and hence the two transverse semicurved lines of abrasion, about four inches long and two inches apart, which were plainly noticeable on my examination.

Wimpole-street.

AN INFECTIOUS FORM OF PNEUMONIA.

By A. WYNTER BLYTH, M.R.C.S., F.C.S.,
FELL. ROY. HIST. SOC., ANALYST TO COUNTY OF DEVON, MEDICAL OFFICER OF HEALTH TO THE NORTH DEVON COMBINED DISTRICT, ETC.

In medical literature there are a few scattered facts and hesitating assertions with regard to an infectious form of pneumonia, or, at all events, one that assumes an epidemic aspect. Thus Dr. Parkes says:—"Considering that the pleuro-pneumonia of cattle is propagated through the pus- and epithelium-cells of the sputa passing into the air-cells of the cattle, that even in man there *is evidence of a pneumonia or phthisical disease being contagious*, the floating of these cells in the air is worthy of all attention."*

Greisinger also has observed that in malarious districts pneumonia is apt to assume an epidemic form,† and Dr. Aitken remarks that it is a disease of general and universal prevalence, *and sometimes appears as if it were epidemic.*‡ When I first came into the North of Devon, Dr. Christian Budd, of North Tawton, called my attention to a form of pneumonia which he asserted was infectious—an opinion which he formed no less than twenty years ago,—and he related many striking instances in support of his assertion. For example, he attended a farmer at Bow who was affected with acute pneumonia, and was nursed during his illness by his niece. His niece became affected with the same disease, and carried it to her husband. In another case, an old man affected with pneumonia reposed on an affectionate relative's breast during a great part of his fatal illness. The relative was very shortly afterwards affected with the same ailment. Dr. C. Budd appears to have been hitherto entirely alone in this belief of the general infectious character of pneumonia; the medical men practising in the same district did not, I believe, put the same interpretation on the striking facts before their eyes, and that gentleman has never published in any form the results of his large experience, which is greatly to be regretted.

During the present year there has, however, been so intense an epidemic of pneumonia in the district that I am connected with, and its infectious character so impressed the medical men that some of them indeed regarded it as a new disease—a sort of new plague. For example, a practitioner of considerable experience, who must have seen hundreds of cases of pneumonia, writes to me thus:—

"The disease alluded to in your letter and annual report has puzzled me much. It is unquestionably a pleuro-pneumonia, which creeps on insidiously first through one day, then the other. At the commencement of the first attack rigors and severe pain in the head, back, and legs, with, in some of the cases, persistent diarrhœa and great cerebral disturbance, have been unfailing symptoms." He then gives a list of cases, which, suppressing names, is as follows:—A man became ill of pneumonia in April, and died after ten days' illness. His wife caught the disease, her first symptoms appearing three days after his death. About the same date a farmer's daughter, living a mile from the house of the former patient, became ill of pneumonia, and five other cases followed, all in the same parish, consisting of a small village and a few scattered houses (population 470). "Since November," continues the writer, "I have had I should think twenty cases. A farmer in another parish became ill on April 16th. I was sent for on April 18th, and he died about midnight. The servant woman went home ill of the same disease about a week afterwards, and gave it to her married sister with whom she was staying."

* Manual of Hygiene, p. 97.
† Infections Krankheiten.
‡ Dr. Aitken's Practice of Medicine.

This short letter then is fair evidence both of its epidemic and infectious character, and the evidence is further strengthened by other considerations, one of which is the extreme inequality of the deaths from pneumonia in the five rural districts as given below:—

Table showing the comparative frequency of Pneumonia as shown by the Deaths in the five Unions in 1874.

	Actual deaths from Pneumonia.	Proportion of deaths from Pneum. per 1000 deaths from all causes.
South Molton ...	20 ...	84
Okehampton ...	14 ...	48
Torrington ...	5 ...	24
Bideford ...	3 ...	22
Dulverton ...	1 ...	14

It should be remembered that these figures do not refer to the boroughs; they exclusively belong to the rural districts; the only one entirely different from the rest in geological features being the Dulverton district, which is in Somersetshire, and belongs to a different watershed.

The great increase of deaths from pneumonia this year may be gathered from the following table.

Table showing the actual Deaths and comparative frequency of Pneumonia during the half-year Jan. 1—June 31, 1875.

	Actual deaths from Pneumonia.	Proportion of deaths from Pneum. per 1000 deaths from all causes.
South Molton ...	15 ...	126
Okehampton ...	20 ...	98
Torrington ...	15 ...	111
Bideford ...	4 ...	71
Dulverton ...	9 ...	144

I do not wish to argue that each of these cases which have been returned as pneumonia was infectious; in all probability there are two common kinds of pneumonia, one possibly arising from cold or the like cause, the other zymotic; and these two forms are at the present time confused together, just as *typhus* and *typhoid* fevers were formerly distinguished by a common appellation. It is a noticeable fact that Grisolle asserted a discoverable cause (that is, in the nature of a chill) could only be affirmed in one-fourth of his cases, Ziemssen in one-tenth of his, and Dr. Wilson Fox could only trace any connexion between exposure to cold and the diseases in 16 out of 53 cases. A consideration of these facts, and also one or two isolated instances of pneumonia occurring in fœtal life,* has so far influenced medical opinion that ordinary pneumonia is, I believe, by the majority, considered as a blood disease, which the remarkable fall of temperature after the effusion has been poured into the lung, the frequent occurrence of albumen in the urine, and its whole course, unmistakably point to. Once considered as a blood disease, it is but a step to the idea of infection; but this idea of infection has hitherto been too hastily thrust aside, in a great measure from the frequency of a pneumonia as a complication of blood disorders. For example, it has been noticed in scarlatina, typhus, typhoid and rheumatic fevers, glanders, farcy, septicæmia, and erysipelas, and an inflammation of the lung is not uncommon in kidney diseases when the blood is loaded with effete products. In thus allowing that inflammations of the lung may be produced by a variety of causes, this admission in no single degree negatives the idea of a specific lung disease, in which the seat of election to which the poison determines is the air-cells; so that just as scarlet fever determines to the skin, typhoid fever to the bowel, hydrophobia to the spinal cord, the pneumonic germ culminates in the pulmonary tissues. Besides, there is an infectious pleuro-pneumonia in cattle, and just as we have a small-pox and sheep have a small-pox, and just as we have a scarlet fever and horses have a scarlet fever (strangles), and as we have a typhoid fever and animals have a typhoid fever, all of these not identical, all of these probably not communicable from one species to the other, but strictly analogous; so if it be established that man is affected with an infectious pleuro-pneumonia, it will only add another link in the mighty chain of evidence of the intimate connexion of the animal and human organisms.

With the powerful aids to clinical research of the present day, surely it is not too much to hope that the separation and identification of this form of pneumonia are not impossible. That such a form exists, *infectious, zymotic, self-propagating*, I feel in my own mind convinced.

A CASE OF

RUPTURE OF THE RIGHT MEMBRANA TYMPANI DURING AN ATTACK OF VOMITING.*

BY H. BENDELACK HEWETSON, M.R.C.S.

MR. G. T——, aged forty-eight, consulted me in February last on account of deafness of the right ear attended by considerable and very persistent noises in the head. On inquiry I found that in the early part of November of the previous year he had suffered from a severe attack of retching and bilious vomiting. This having ceased, he discovered himself to be deaf of his right ear, which previous to the attack had been quite good. On his first finding that the ear was deaf he attempted to hear his own watch, but failed to do so, even when it was pressed close to the ear. Thinking from the absence of pain that the deafness would prove to be temporary, he delayed obtaining any advice until Feb. 23rd, 1875. At that time there was no discharge from the ear, the external meatus was healthy, as also the tympanum appeared to be, with the exception of a dark speck on the membrane lying slightly in front of the handle of the malleus, midway between that process and the edge of the drum. Air could be heard to enter the Eustachian tube and tympanic cavity during the act of deglutition, but no air passed out of the external ear through an opening in the drum when the tympanic cavity was forcibly inflated by a closure of the mouth and nose.

I suspected, however, the existence of a rent in the drum, from the fact that a slight streak extended upwards and downwards from the spot on the membrane.

After syringing the ear with warm water, and again inflating the tympanic cavity as before, air was expelled from the ear through a perforation in the drum, accompanied by a loud hissing sound.

The speck was, then, clearly some secretion which had stopped the exit of air and also prevented the close apposition of the edges of the tear, thus interfering with their union, the white streak above and below the speck being the extremities of the wound which had cicatrised. The syringing had removed the secretion, allowing the air free exit, during which the edges of the rent could be seen to separate. The watch was only heard when pressed upon the right mastoid process, and the ordinary voice, with the left ear stopped, was not heard at all. I recommended that the ear be syringed with a warm slightly alkaline solution of bicarbonate of soda, and that drops containing sulphate of zinc, in the proportion of three grains to the ounce of water, should be used thrice daily after syringing.

On March 2nd, 1875, after eight days of the above treatment, the rent in the tympanum had entirely closed, but if much pressure of air was brought to bear upon it from within, the new cicatricial tissue bulged outwards.

---

* Read before the Leeds and West Riding Medico-Chirurgical Society.

On March 6th the watch was first heard when in contact with the ear, and the ordinary voice could be recognised at a distance of five feet.

A fortnight later the watch was heard at a distance of nine inches from the ear, and the voice at twenty feet. Since that time normal hearing has returned, the only remaining evidence of any previous malady being the cicatrix in the tympanum.

There are obviously several points of interest and practical value connected with this case. It seems clear that air must have been driven violently up the Eustachian tubes during vomiting, or retching, with sufficient force to rupture the right drum. The sharp concussion of air from without caused by the firing of cannon or a blow on the ear has been frequently the cause of a ruptured tympanum; but it seldom occurs that air can accidentally enter the tympanic cavity with enough force to produce such results. The case is interesting, therefore, from its rarity. The excessive deafness attendant upon rents in the tympanum, where there is no loss of substance, appears to be caused by the flaccid condition of the membrane deadening the sound, and preventing its conduction into the internal ear. A large amount of hearing remains in many cases of perforation of the tympanum apparently because the hole is so punched out as not to affect the tension of the drum in so serious a degree as would be the case if it were made flaccid from a rent.

The great power of repair in the tympanum is seen in the above case, as in many others of a like kind which have recovered without any treatment whatever. Some cases, however, do not get well without interference; and it is in those cases in which secretions collect between the lips of the rent, preventing the close approximation of the edges, that the above treatment will prove most efficacious.

Lastly, great care seems to be indicated in inflation of the cavity of the tympanum by Politzer's method in the event of Eustachian obstruction, when that condition complicates a recent rent or a healing perforation of the membrana tympani.

GUY'S HOSPITAL.

CASES ILLUSTRATIVE OF SOME OF THE DISEASES OF THE RECTUM.

(Under the care of Mr. Bryant.)

We this week continue the series commenced on the 4th inst. of cases illustrating some of the diseases of the rectum.

Prolapsus recti of twenty-seven years' standing due to the presence of polypus; removal of polypus; recovery. — (The following notes were taken by Mr. E. W. Deane.) Horace W——, a clerk aged forty-seven, was admitted into Job ward on the 1st of March, 1875. His family history was good, excepting that his father and sister were subject to what he called piles. He himself had tolerably good health, although when twenty years old he first noticed a pain when his bowels were open. Some seventeen years after this the pain had considerably increased, and he noticed that there was something protruding from his anus, which he used to put back. The protrusion occurred not only when he passed a motion, but also when he walked. He consulted surgeons, who treated him with lotions and medicines. His complaint was supposed to be piles, and he was advised to obtain admission to Guy's Hospital, where it was found that he had prolapsus recti. The bowel protruded for about three inches, and the rectum was very loose. Upon examination, a fibrous polypus was detected high up the bowel, which caused the prolapse. A doubled-threaded needle was passed through and tied, and the polypus was removed with a pair of scissors. A morphia suppository was placed in the rectum, and a subcutaneous injection given, after which he passed a good night. His progress towards recovery was uninterrupted. On the 16th of March a piece of protruding flesh was removed. There was slight bleeding, but he was much easier, and the following day he left the hospital nearly well.

Stricture of rectum; colotomy; convalescence.—(The following notes were taken by Mr. Chadd Johnson.) Mary Ann S——, aged thirty-six, was admitted into Lydia ward on the 12th August, 1873. Six years before she was troubled with piles, and passed her fæces with pain and difficulty. A year after she often passed blood and mucus, followed by diarrhœa; this continued, and she consulted a medical man. For nine weeks before admission she had been in great pain, but was able to pass her motions without medicine. She noticed, however, for some time, that the fæces had gradually become smaller.

On examination, the last three or four inches of the rectum were ulcerated and strictured, so that a urethral bougie (No. 10) could with difficulty be passed up the rectum.

She had been twice married. By her first husband, who was a sailor, she had one child, who died of thrush three weeks after birth; she also had two miscarriages. Her second husband was alive and healthy. She had no other children.

On August 19th colotomy was performed, the patient being put under the influence of chloroform. An oblique incision was made across the left quadratus lumborum muscle, the lumbar fascia was divided, and the descending colon caught and firmly ligatured to the edges of the wound, and then the posterior part of the colon was opened. The colon was moderately distended with fæcal matter. She had a good deal of sickness during the night, and complained of pain in her back. Pulse 106; temperature 100·2°.

Aug. 27th.—She fancied there was a well by her bedside; her appetite was better; her bowels had been opened; she passed a lot of purulent-looking water and wind per rectum, and again the next day she said she felt better, and seemed quieter.

Sept. 3rd.—The motions had passed freely by the opening; there had been no fæcal matter by rectum for two days. Pulse 116. She was ordered bark and iron.

11th.—She passed a restless night, and complained of shooting pains through the side; her head ached and she felt languid; a good deal of matter came away per anum; she was, however, better on the following day.

18th.—She had been progressing very well, and was sitting up. From this date to the day of her discharge she continued to improve. She was examined locally; there was no thickening nor ulceration, a little pus coming away occasionally. She left the hospital on the 10th Oct.

Since the patient left the hospital, the cancerous disease of the rectum has progressed, and has involved the buttock. The bowels act regularly through the artificial anus, and the woman was comparatively comfortable nearly ten months after the operation.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.

CASES OF GLAUCOMA.

The following cases, for the notes of which we are indebted to Mr. Geo. Ernest Alford, complete the series commenced at page 345.

Case 4. *Acute glaucoma; iridectomy; cataract.*—(Under the care of Mr. Hogg.) S. S——, aged fifty-one, was admitted Feb. 4th. He said he had not been able to see light with his left eye for six weeks, and that he had had violent pains of a neuralgic character in the eye and in side of the face during that time. The pain came on suddenly, and the sight was entirely lost within a week from the time he first noticed that something was the matter with his eye. He was also very deaf, but had only been so since the eye became affected.

When admitted, there was no perception of light in the affected eye. The fundus was invisible; the pupil dilated, fixed, and of a greenish hue. He complained of violent pain in the eye and head. The tension was much increased —T + 2.

Under chloroform, Mr. Hogg did an iridectomy upwards and inwards in the usual way. Only a small piece of iris was removed. Atropine was instilled, and a pad and bandage applied to both eyes. In the evening more atropine was dropped into the eye. There was great pain in the eye for the next day or two, and the patient slept badly. He was ordered ten grains of iodide of potassium, with the bromide of potassium and bark, which subdued the pain. As he still slept badly, he was given ten grains of compound ipecacuanha powder on the 21st, and a few days afterwards, the pain having returned, one-third of a grain of acetate of morphia was injected hypodermically into the left temple with great benefit. On the 4th of March the pupil was quite clear, but the eye was still very tense and painful, so that Mr. Hogg removed a large piece of the iris upwards and outwards under chloroform. The eye bled very freely. This relieved the pain very much and lessened the tension. He went out on March 19th, still unable to see the light, but with no pain. He returned, and was readmitted on April 8th. There was a distinct cataract pressing the iris forwards. The pain had returned with increased severity, and the globe was very tense. Under chloroform Mr. Hogg removed the lens with a spoon through an incision at the upper margin of the cornea. The cataract was rather soft and much swollen. He had no more pain after the operation. The wound healed well. On April 23rd he went out, and although no vision had been recovered, he had had no return of the pain.

Case 5. *Acute glaucoma; iridectomy; extirpation.* (Under the care of Mr. Power.)—Thomas M——, aged forty-eight, labourer, was admitted on February 8th. The right eye had been affected only during the previous six weeks, and he had completely lost all vision in it a few days after it was first attacked. On admission he was unable to see the light with it, and had violent pain in the eye and head. Fundus invisible. To relieve the suffering, Mr. Power did an iridectomy upwards without chloroform, removing a large piece of iris. There was scarcely any bleeding at the time, but the anterior chamber was full of blood by the next morning. This was, however, soon absorbed, and by the 22nd the pupil was quite clear, and the globe no longer tense. He had very little pain after the operation. As some irritation was caused by the lashes of the lower lid being inverted, Mr. Power removed on March 5th an elliptical piece of skin close to the lashes, and brought the edges of the wound together with sutures. The wound healed very well, and completely cured the complaint. On March 11th he went out, with no pain in the eye, but still unable to see the light.

He was readmitted on April 19th. The pains had returned with increased severity; the eye was red and watery, very tense, and the pupil was of a deep greenish hue. The left eye was getting weak, and the vision failing. On April 23rd the right eye was extirpated, under chloroform, in the usual way. There was a great deal of ecchymosis afterwards, but this soon subsided, and the wound healed well. The patient had no more pain, and the other eye became as strong as ever. He went out on May 1st. On examining the extirpated eye a staphylomatous protrusion was found at the upper and inner part of the equator of the globe. At this point the sclerotic was very thin (about one-fourth of its normal thickness) and bluish. The retina was spotted all over with small hæmorrhages, and its vessels were large and tortuous. The optic disc was very much cupped. The retina was atrophied, and the large choroidal vessels showed through it distinctly. The vitreous humour was very fluid, and the lens quite clear.

Case 6. *Simple glaucoma; iridectomy; cure.* (Under the care of Mr. Cowell.)—Martha H——, aged forty-eight, married, was admitted Feb. 26th. She stated that four years ago she fell and struck her back against a fender, and that since then the sight of the left eye had been gradually failing; it had been getting rapidly worse during the last few months. She had had continuous pain in the eye and head, preventing any sound sleep and taking away her appetite. The sight, she said, was sometimes very much less acute than at others. She was very much constipated, and had frequently taken pills daily for a week before she could obtain relief; she was also very subject to rheumatism, and had had a great deal of trouble and worry during the last few years. She used No. 7 convex glasses for both eyes to enable her to read. With them she read at the time of admission No. 5 Snellen, and her vision was $\frac{20}{70}$ with the right eye; with the left she read No. 20 Snellen, and her vision was $\frac{20}{100}$. The right eye was hard: T+1. There was distinct cupping; media slightly hazy. The left eye was of stony hardness; T + 3; media very thick, just allowing the fundus to be obscurely seen; the disc was deeply cupped, looking like a pit, into which one or two vessels were dimly seen to disappear; the iris was pushed forward; lens clear; pupil dilated, sluggish and greenish. The patient saw halos round lights with both eyes. The field of vision was narrowed, especially in left.

On Feb. 27th Mr. Cowell made a small iridectomy upwards in left eye, without any anæsthetic. A pad and bandage were applied. She had no pain in the evening, and slept better than she had done for many weeks. The eye was bathed daily with warm water, and uncovered altogether on the sixth day. During this time she had had no pain, had slept well without any draughts, and her appetite had returned. She went out on March 6th, the eye looking quite healthy; no tension, no cupping, and a perfectly clear pupil, and the *right* disc was no longer cupped. Her vision was:—*Right* eye, $V = \frac{20}{70}$; with convex 10, $V = \frac{20}{30}$; with convex 7 she read No. 1. *Left*, $V = \frac{20}{100}$; with convex 10, $V = \frac{20}{70}$; with convex 7 she read No. 4.

On March 17th, with convex 7 she read No. 3 with left eye. She had had no more pain, and both eyes seemed to be getting stronger and clearer every day.

Case 7. *Subacute glaucoma; iridectomy; partial recovery.* (Under the care of Mr. Power.)—Elizabeth S——, aged fifty-nine, married, was admitted on March 27th, 1875. She said that the left eye had been getting dim for six months. The first thing she noticed was that in looking at a candle she saw circles of light round it. She had not suffered very much pain in the eye at any time, and it had not prevented her sleeping well. She was not at all subject to rheumatism or gout. Her health had always been good, and her bowels were regular, and she had had no great trouble lately. On admission there were a slightly marked circum-corneal zone, and a greenish hazy look about the pupil, and the iris was dilated and immovable; tension considerably increased (T + 1 or 2), and there was some hypermetropia. The media were too hazy to permit of an examination of the fundus. In the right eye the media were also hazy, but the disc could be seen to be free from cupping, and with its vessels very small. With the left eye she could only just distinguish light and shade. On March 29th Mr. Power did an iridectomy upwards, of moderate size, which was attended with no hæmorrhage, and which formed a pupil of the orthodox "key" shape. Atropine was instilled, and a pad and bandage were applied to both eyes. The eye was bathed daily, and atropine was dropped in; she had no pain in the eye, and she slept well. On the second day the right eye was uncovered, and on the third a shade only was worn, as the wound had quite healed. She was discharged on April 5th, with the pupil still slightly hazy. She had no pain, and was able to count fingers at two feet distance.

On April 9th (twelve days after the operation) the media were nearly clear, there was still slight cupping, the tension was normal, she could see all large objects about the room sufficiently well to enable her to walk about when the right eye was covered, and vision seemed to be improving daily. The right eye had completely recovered.

She has not been seen at the hospital since the above date.

A few general remarks on the above cases may not be out of place. In almost all, as is so commonly the case with hospital patients, the operation was performed too late to achieve the perfect success which almost invariably attends iridectomy for glaucoma when this plan of treatment is early adopted. Although vision was not much improved in some of the cases, yet in each there was much abatement of the pain,—in all temporarily, in most permanently. This fact alone would sufficiently justify the operation, as the pain is usually of the most violent description, preventing sleep, taking away the appetite, and rapidly weakening the patient. It may be added, that most of these cases had been previously under treatment by lotions and general measures, which had, of course, done nothing towards relieving the complaint. It is scarcely saying too much that, had they all come to the hospital when the disease commenced, they would all at present be enjoying good sight, instead of the majority being nearly blind. Probably there is no operation in surgery the early performance of which is so important as that of iridectomy in glaucoma.

EDINBURGH ROYAL INFIRMARY.

ANÆSTHETIC LEPROSY OF THE LEFT ARM; AMPUTATION AT SHOULDER-JOINT; RECOVERY.

(Under the care of Mr. Joseph Bell.)

For the notes of the following interesting case we are indebted to Mr. Holland J. Cotton.

Sarah M——, aged thirty-five, a widow, was admitted March 20th, 1875, suffering from a form of leprosy of the left arm and hand. She had had nine children, all of whom had died in infancy except one little girl, who was quite healthy, and betrayed no sign of hereditary syphilis. The husband was a healthy labouring man up to the time of his death, which occurred suddenly a few months ago of bronchitis. The patient herself looked delicate and despondent, but had always enjoyed good health until four years ago, when the disease first showed itself as two hard lumps just below the shoulder. These apparently ran through stages similar to gummata, and were followed by others lower down the arm, but in time they all ulcerated and cicatrised over. Two years later similar lumps appeared in the same region, and gradually spread down the forearm to the hand. These ulcerated as before, healing up above and then breaking out lower down, so that at the time of her admission into the hospital the whole hand was involved and was of great size. The patient had never been out of the vicinity of Edinburgh, and would admit nothing that would lead to the suspicion of syphilis.

The elbow-joint was found to be anchylosed at a right angle, and the arm slightly atrophied, and covered all over with cicatricial tissue, which broke down on the slightest irritation. The hand was much hypertrophied, and covered with a rough, hard, tubercular skin on the dorsum, which at one part seemed to be quite calcareous; whilst the fingers resembled most the tubers of a potato joined together, with claw-like nails hanging on. The middle and ring fingers were suppurating at the tips and exuding fetid matter; and the little finger had not enlarged, but was flexed on the palm. The limb was heavy, and the patient was very anxious to be rid of such a loathsome encumbrance. Accordingly, Mr. Bell, believing the case to be one of tubercular anæsthetic leprosy, amputated the limb at the shoulder-joint, but was compelled to make use of some of the cicatricial tissue in order to get flaps, so closely had the disease approached the trunk. Hardly any blood was lost at the operation. A drainage-tube was passed through the wound, and antiseptic dressings adopted.

The patient progressed most favourably, the pulse and temperature scarcely ever rising above normal, whilst at the daily dressing no discharge was found, but only serous oozing. The upper part of the wound healed by first intention, but the lower part included the portion of cicatricial tissue, and this formed a small slough, and separated in shreds, thus preventing the wound from being altogether antiseptic. Within a week of the operation the patient was very anxious to get up, but this was not allowed till ten days later, when all fear of secondary hæmorrhage had passed. The patient's general appearance and health improved greatly, but, owing to the sluggish character of the granulations which covered the small surface still unhealed, she was detained in hospital till the first week in May, when she was discharged quite cured.

DEVIZES COTTAGE HOSPITAL.

LIGATURE OF THE EXTERNAL ILIAC.

(Under the care of E. N. Carless, M.B.)

Henry ——, aged twenty-nine, a carpenter's labourer, was admitted on November 18th, 1874. Two months previous to his admission he noticed a swelling in the thigh, the size of a bean, which gradually increased.

According to the patient's statement he had suffered from syphilis some ten years before.

On examination, a pulsating tumour, the size of a Seville orange, with well-marked bruit and eccentric distension, occupied the middle of Scarpa's triangle. Treatment by compression was first resorted to, and the means used consisted of Signoroni's tourniquet applied to the femoral artery above the aneurism.

During three days, compression in this way was obtained for about three hours night and morning, with the result that, at the end of this time, the aneurismal tumour was observed to become smaller, harder to the touch, and the bruit less distinct. Under these circumstances this method of treatment would have been continued had not the patient at this time, on account of the pain which he experienced from the pressure, persisted in unscrewing the instrument and taking off the pressure.

After this, the tumour having rapidly increased, ligature of the external iliac artery was decided upon, but it was not until January 16th that the objection of the patient to the operation could be overcome, and accordingly on the following day ligature of the artery was performed. The tumour had attained the size of a fœtal head, and occupied the whole of Scarpa's triangle. The thigh measured, over the tumour, 24¼ in.; the other thigh measured 18¼ in. At 11 o'clock the external iliac artery was ligatured with a double thickness of carbolised catgut. The wound was brought together with three silver-wire sutures, and dressed with carbolic acid and oil. Carbolised tow was used as a pad; the limb was raised and enveloped in cotton wool. At 3.30 p.m. the patient complained of a slight feeling of cramp in the foot; no pain. At 8 p.m. no pain; bowels have been moved. Pulse 92; temperature of leg, 98°.

Jan. 18th.—10 a.m.: Has had no sleep. Tongue clean; pulse 92; temperature of leg 97·5°. Ordered five grains of compound soap-pill every three hours.—8 p.m.: Has had sleep. Temperature of leg 99°; pulse 88.

19th.—Slept well during night. Appetite good; takes beef-tea, milk, and soda-water. Thigh measures 23 in. A few drops of pus at outer corner of wound.

20th.—Thigh measures 22½ in. One suture removed.

22nd.—Remaining sutures removed.

28th.—Thigh measures 22 in.

Feb. 2nd.—Wound perfectly healed.

5th.—A small livid patch presented itself on the centre of the tumour, about the size of a shilling. Complains of pain in tumour. Tumour to be poulticed.

12th. — Tumour freely opened, when a considerable quantity of dark fetid discharge escaped.

20th.—Wound still discharging.

March 17th.—Dismissed cured.

August 11th.—Patient has been engaged at his usual employment since May, and is quite well.

Reviews and Notices of Books.

Diseases of the Kidney and Urinary Derangements. By W. H. Dickinson, M.D. Cantab., F.R.C.P. In Three Parts. Part I. Diabetes. London: Longmans. 1875.

Dr. Dickinson's treatise on Diabetes is intended to be the first instalment of a work on Diseases of the Kidney, of which the second is to consist of his account of Albuminuria, published some years ago, and now out of print. The character and scope of the latter are well known. The present volume is equally useful. It is so arranged as to be available for the student, the practitioner, or the scientific physician. A preliminary chapter on the physiology of glycogenesis and glycosuria discusses the various systemic relations of the subject; its pathological anatomy and pathology are next considered, and then its causes, symptoms, and treatment. The cases which illustrate the preceding statements are described at length in a separate chapter. The effect is to clear the pages of much loose material, which in some works is so great an obstacle to their convenient use. Diabetes Insipidus forms the subject of three concluding chapters.

The abundant investigations into the physiological relations of the excretion of sugar, with which the names of Bernard, Schiff, and Pavy are especially associated, have undoubtedly brought us a great and important step nearer to the comprehension of the real nature of diabetes. The account of these investigations is carefully and accurately written. It is not, indeed, a very full discussion of the numerous problems, primary and collateral, which are involved in the order and disorder of the formation and excretion of sugar, but it has the merit of advancing nearly all that is known with any approach to certainty.

The pathology of the disease is essentially a comparative one. It rests entirely on the facts of experimental research, every fact having been obtained at the cost of numerous experimental observations on the lower animals. The application of the results thus obtained to man has some, though probably only few, elements of uncertainty. There is little or nothing that is fresh in the description which Dr. Dickinson gives of the observations on the glycogenic functions of the liver and its derangements. He rejects, as unsubstantiated by clinical observations, all theories of diabetes which refer it to lessened consumption of sugar formed in the body in normal amount. Of these theories much has been and may be said, which the author has wisely omitted, since very little practical counterpart can be offered. Various conditions influencing increased supply are more fully considered. That view of the disease is accepted as most consistent with our present knowledge which regards its essential feature as perversion of hepatic function which, while it does not hinder, and possibly exaggerates, the disruption of protein bodies, substitutes in the issue sugar for glycogen. "Thus the material which should be retained as glycogen to form sugar only in small proportion, while it ministers in other ways to nutrition, is replaced by sugar, of which the bulk is necessarily expelled."

The pathological anatomy of the disease is described at length. The morbid changes were few until Dr. Dickinson's researches extended the range in which they are to be found by his discovery of alterations in the nervous centres. A considerable space is devoted to a description of these changes, which are so important and so constant as to justify, in the author's opinion, the inclusion of all cases of the disease as examples of an affection of the nervous system. He has examined the brain and cord in eleven cases of diabetes, and has found morbid changes in all. They consist of excavations about the arteries, or in the positions which arteries once occupied, the excavation being due to destruction of the adjacent nervous substance. The initial step is supposed to be the escape of corpuscles by migration, and subsequent changes in the tissue into which they pass. They occur chiefly in the optic thalami, corpora striata, pons, medulla, and cerebellum, and are also found in the white matter of the convolutions. They contain a translucent gelatinous material, or the products of granular degeneration of the tissue. The changes in the cord are similar, but less declared. Erosions around arteries are seen, especially in the transverse commissure, and occasionally in the grey substance. The central canal is often dilated. In one case patches of "miliary sclerosis" were found throughout the brain and cord. It has seemed to some that these changes are rather secondary to the morbid state of the blood than its cause. Against this view it is urged, however, that diabetic blood is not generally irritating to the tissues. Atheroma and vascular degeneration are strikingly rare in diabetes. The pulmonary change is peculiar to the lung rather than concurrent with similar changes elsewhere. The changes are apparent along the course of arteries rather than in the region of capillaries, where the mischief produced by a blood state would probably first show itself; and the process by which the alterations are produced, as far as can be discerned, points to an alteration, not in the quality, but in the distribution of the blood, as its first step. The changes in the nervous system are not special to diabetes; they are common to many other diseases of the nerve-centres: it is their special localisation in certain regions which sets up the morbid processes resulting in glycosuria. The nature of the change in the nerve-centres is hypothetically to irritate rather than to paralyse, and this accords with the evidence of experiments on animals. Irritation rather than loss of function seems to be the special effect of the nervous changes which, artificially produced, lead to the disease.

It is difficult, however, to believe that these facts furnish an adequate explanation of the nature of diabetes. The disease presents, in its clinical associations, no real alliance with diseases of the nervous system. Transient glycosuria may be, and often is, a result of morbid changes in a certain part of the cerebro-spinal centre, but these cases are very different in their character and course from those commonly included under the term diabetes, in which the glycosuria is progressive and often of great amount. In the latter cases, too, it is rare to meet with obvious nervous symptoms. If the minute changes which are scattered through the nervous system interfere so absolutely with the functions of one part of the nervous system as to lead to the severe form of diabetes, they should elsewhere cause other symptoms. If their occurrence is of the serious nature which Dr. Dickinson assumes, various paralyses and interference with mental power might reasonably be expected to be apparent. Instead of this we have only a gradual loss of physical strength uniform and equal, and much more suggestive of a blood than of a primarily nervous cause.

The pathological anatomy of the other organs is fully described, but does not receive any important additions. The changes in the liver are regarded, from their character, as probably secondary to vascular disturbance. The lung affection, so common in the disease, is rarely the result of true tubercle, being in most cases inflammatory in its origin.

To this chapter is appended, as important in connexion with the changes in the nervous centres, an account of the examination of the urine in a considerable number of cases of insanity. In such cases it is well known that alterations in the brain and cord, similar to those found by Dr. Dickinson in diabetes, are not uncommon. The investigation yielded the very remarkable result that in 106 cases of various forms of insanity, no less than 47 presented sugar in the urine. The grounds on which the statement is made are not, however, beyond question. Only 3 cases out of the 47 showed a considerable reduction of Fehling's solution. Of the remainder, 29 only showed a "trace of reduction." By this is meant that the colour was discharged when a mixture of two parts of urine and one part of Fehling's solution were boiled together. In the remaining 15 the test showed a "decided reduction"—i.e., a discharge of colour occurred when equal parts of the solution and of the urine were boiled together. It is doubtful whether the former test can be taken as evidence of even the slightest trace of sugar. No doubt the presence of the quantity it is supposed to indicate (1·2 per cent.) will cause the reduction as described, but it by no means follows that such reduction is evidence of that quantity, or, indeed, of any sugar at all. The normal urine has been shown to contain small quantities of substances capable of reducing copper, if the quantity of the urine is greater than that of the solution used. Kühne's assertion that the urine contains 1 per cent. of sugar—a statement not to be overlooked in estimating Dr. Dickinson's facts—has been shown by Seegen to be open to grave question. Seegen believes that the reduction attributed by Kühne to sugar is due in great part to other substances capable of reducing Fehling's solution, and that the quantity of sugar in normal urine must not be estimated at more than ·03 per cent. Dr. Dickinson's cautious mode of expression indicates, indeed, that he is aware that his results cannot be accepted as so conclusive as in a subsequent paragraph he assumes that they are.

The account of the etiological conditions and symptoms of diabetes is excellent. A careful and interesting comparison has been made of the geographical distribution of the disease in England and Wales, which seems to indicate that it is more abundant in the agricultural districts than where the inhabitants are engaged in manufactures and mining, and that it is more abundant in the colder than in the warmer counties. It is not especially frequent where ague abounds nor where cider is drunk. It is more common among tillers of the soil than among miners or manufacturers similarly situated.

Dr. Dickinson's observations support the theory of Prof. Haughton, that there is a relation between the production of sugar and of urea in the organism, the two being supposed to be the common product of the decomposition of albumen. The urea and the sugar in the urine increase and diminish together—a relation which points clearly to a community of origin. It is intimated that the excess of urea bears to the sugar very much the proportion which it should theoretically present—i.e., one to five.

On the treatment of diabetes Dr. Dickinson has nothing new to add. He gives a convenient dietary table, arranging in parallel columns what to eat, what to drink, and what to avoid, and appends the additions to the strict diet which constitute a modified regimen. He adds his testimony to the very general condemnation which the "skim-milk treatment" has received. Of drugs, he has found strychnine the most useful, and places cod-liver oil next in value.

The chapters on Diabetes Insipidus, with which the work closes, contain a good account of that curious disease. The author has made some interesting experiments on the effect of diet on the malady. The presence of diabetes insipidus in children, in whom the saccharine form is so rare, suggested a possibility that the two diseases might be essentially one, influenced by the varying conditions under which it occurs. It was therefore tried whether, by a very starchy diet, the insipid could be converted into the saccharine form. The result was negative, and the conclusion is drawn that the diseases are essentially different. An interesting case is narrated, in which polyuria resulted from pressure upon the abdominal sympathetic.

The book is illustrated by some well-executed woodcuts and lithographic plates of the morbid changes in the nerve-centres and other organs.

The Medical Vocabulary: containing a concise Explanation of the Terms used in Medicine, &c. By R. Fowler, M.D. Second Edition. pp. 552. London: Renshaw. 1875.

The preparation of a medical dictionary is a task that seldom brings much credit to the author. The difficulties of successful definition, in the face of the shifting opinions regarding diseases and their causes, alone suffice to explain the fact. In the vocabulary form of dictionary, however, conciseness is the most essential element, but this must not be secured at the expense of clearness and sufficiency of meaning. Bearing these points in mind, we are able to speak well of this second edition of Dr. Fowler's work, which exhibits the results of great care in its composition. Since the publication of the first edition two events affecting scientific terminology have happened—namely, the publication of an authoritative "Nomenclature of Diseases" by the College of Physicians of London, and the acceptance by chemists of important innovations in chemical nomenclature. Dr. Fowler's work bears the impress of these two advances in modern terminology. The author has also added a list of the ordinary medical terms in common use with their Indian synonyms (in the Roman character), with the view of rendering the vocabulary of use to those who are studying for, or practising, in our eastern dependencies.

The type of the work is good and particularly clear, and the eye at once catches the words which stand as the headings of the definitions.

The vocabulary is a good one, and we again commend it to the medical reader, on account both of its conciseness and its correctness.

REPORT
OF
The Lancet Commission
ON THE
SANITARY CONDITION OF OUR PUBLIC SCHOOLS.

WINCHESTER.

St. Mary's College, Winchester, is the oldest public school in the kingdom. It was founded in 1387 by William of Wykeham, and for many years the scholastic institutions subsequently established were generally modeled on the Winchester system. The management is vested in a warden, the head master, the fellows, and the governing body. The school contains, on an average, about 300 pupils; of whom 70 are foundation scholars, formerly called "the children," and 250 commoners or boarders who pay for their board and education. The former sleep in the college, in seven large dormitories as old as the college buildings, on oaken bedsteads two centuries old; and eat their dinners off trenchers of wood, and we believe still drink their ale from the old "black jack." They are lodged, boarded, and educated without expense. The commoners are, so to speak, extra collegiate: they receive the same education as the scholars in the college schoolroom, but they live outside the college buildings, either in the head-master's house or in the houses of the assistant-masters, which are more or less distributed throughout the town.

The college buildings consist of two quadrangles, formed by the dormitories, the library, the dining hall, and the kitchen offices. A school-room, lavatories, urinals, privies, racket-courts, and a sanatorium, complete the premises. The dormitories, as we have said above, are as old as the building; they are somewhat low, but as none of them hold more than thirteen beds the cubic space is amply sufficient; they are kept scrupulously clean, and are held in high esteem and veneration by the boys themselves. The dining hall is a fine room, and the kitchen arrangements are all that they should be. Some years ago there were great complaints with regard to the food, especially the dinners, served to the scholars, and the manner in which it was served; from inquiries made among those who have recently left the school we believe that matters have greatly improved in this respect, as they have at Eton, where similar complaints were made. The schoolroom where the lessons are prepared, as well as recited, is a lofty, well-proportioned room; it struck us, however, the light might be better arranged. The sanatorium is comparatively a new building. It is satisfactory to state that, though cases of scarlet fever have been imported into the school within the last five or six years, there has been no spread of the disease among the other boys. The privies at present are extremely primitive; their contents fall directly into a running stream, which passes through the college grounds, and which in many places passes directly under the college buildings. This stream is derived from a larger, known as Lower Brook, which passes as an open sewer directly past the college gates; this Lower Brook practically receives the sewage of half the lower part of the town of Winchester. We understand the school authorities intend to provide earth-closets instead of the present privies, and also to divert the course of the stream passing through the college grounds; but we fear it will be impossible to restrain the town authorities from continuing to permit pollution of the Lower Brook, which must remain for some time to come an unsafe and unpleasant neighbour. The urinals in the college premises might be improved with advantage. The water-supply of the college is derived from two sources: the first and most used is the water supplied by the town water-works, which is of excellent quality, and is taken from a deep well in the chalk, and there is no danger of its becoming polluted; the other, which supplies the kitchen, jointly with the other service, is derived from the other side of the river, and we were not sure but that at times it might receive chance contamination, and we should advise its discontinuance. The college buildings are situated on the broad meadows which intervene between the river and the foot of the chalk downs, on which the principal part of the town is built. The soil consists of a bed of gravel and peat, about eighteen feet in depth, resting on the chalk. From the lowness of the situation, and from damming back of the river by the numerous mill heads, which hinders the natural drainage, the playing-grounds are not so dry as they ought to be. This should be remedied by artificial drainage, so as quickly to carry off the surface water. The school premises are situated quite at the outskirts of the town, and, if it were not for the abominable Lower Brook, would be quite independent of it with respect to sanitary matters.

The commoners reside in boarding-houses kept by the masters. The chief house belongs to the head master, and is situate in close proximity to the college buildings; and the sanitary arrangements and conditions are much the same. The houses of the other masters are nearer the town. These houses were private property, and no supervision was exercised over their arrangements. Now the governing body, in order to secure uniformity of management and a thoroughly good sanitary condition, have determined to buy up these houses, and relet them to the masters under certain specified conditions. In the houses that have, up to this time, been purchased by the governing body considerable improvements have been effected, and some are perfect models of construction and arrangement. The system of earth-closets has been generally introduced, and the system is to be extended to all the other houses and to the college buildings. Schoolmasters, who may be desirous of isolating their school from a defective and imperfect town drainage, should visit the new boarding-houses at Winchester and see the admirable manner in which the system is carried out. The domestic arrangement at the boarding-houses is excellent, and the diet good and abundant.

There is no regular medical supervision. There are three doctors nominally attached to the school, and the house master chooses which he prefers, when there is actual illness in his house. No regular medical certificate is required on a boy's entering the school, having reference to his physical condition and the nature of his previous illnesses, and it is left to the discretion of the house master to make such inquiries; nor are the parents required to furnish any certificate declaring that the boy has been free from zymotic disease, or been brought in contact with such disease during the holidays. There is no medical inspection on the boy's return to school, so that ringworm, scabies, scarlet fever, &c., might readily be introduced if any parent ignorantly or wilfully returned a boy suffering from such diseases back to school. As the boys only come under the care of the medical men when suffering from actual illness, nothing can be known of the actual condition of a boy prior to such illness. We have shown at Marlborough how excellently the system of medical supervision is worked there, and the advantages that the school has derived from it; how in many instances cases of actual breakdown have been avoided, and how, by timely removal for a term or so, a boy has been able to tide over his school career satisfactorily. We think the governing body at Winchester ought to adopt some such system. With the services of three medical men at their command, there could be no difficulty in having the foregoing particulars attended to, and a supervision as thorough as that of Marlborough instituted. The arrangement of the dormitories at Winchester is excellent. These contain, on an average, nine beds for boys of all ages; there is also a general sitting-room in each house, and a few studies for the senior boys. The hours of work are not excessive: two days a week a boy is in school six or seven hours, on other days four or five; sixth-form boys, however, when preparing for an examination may spend eight or nine hours; all lessons, as a rule, are prepared in the school-room. The system of fagging is more fully carried out at Winchester than at the other public schools, and even here it has been greatly modified of late years. The system is somewhat complicated, and it is difficult to understand the details. We could not learn, however, that it was in any way injurious to a boy who was fitted to be at a public school at all. We know that many parents object to the system, but we think, if carried out with proper supervision, it serves as a restraint in some measure to the growing luxury of schoolboy life, and taking the opinion of "fags" generally, we think it would be found they themselves are not at all averse to it.

In conclusion, we are able to state that the sanitary arrangements and condition of the school at Winchester are, on the whole, satisfactory (we wish we could say the same of the town), and show a marked improvement in this respect to its state some few years back, when it had a very bad reputation for ill-health; so much so, that the commoners in 1858 were reduced in number to 68. The fact that in the last ten years there have been only two deaths from zymotic disease in the whole school, and that no outbreak of scarlet fever has occurred now for some years, though several cases have been imported, and a serious epidemic occurred in the town about two years ago, speaks very favourably for the general management. The arrangement of the dormitories is most judicious; the number of beds is sufficiently large to afford protection against the possibility of immoral practices being even secretly carried out, whilst the number is not so great as to cause danger from the spread of zymotic disease casually introduced. What Winchester most requires is a thorough and complete system of medical supervision. Many of the younger schools have long since recognised the importance of this, and we feel convinced that Winchester cannot much longer delay following their example.

THE NEW HUMAN FLUKE.

To the Editor of THE LANCET.

SIR,—Professor McConnell's description of another human fluke, as given in your pages for August 21st, is of such high interest to helminthologists that I trust you will permit me space enough to say a few words on the subject. Without doubt the species is new to science, and ought to have some distinctive name by which it may be recognised amongst the trematodes. I propose to call it *Distoma sinense.* The evidence adduced by Dr. McConnell in proof of the specific distinctness of his entozoon is overwhelming, and his account of the parasite's anatomical structure presents features of special import. In regard, however, to the flukes obtained by Dr. J. G. Kerr, I have no doubt that they will turn out to be thoroughly characteristic examples of Prof. Busk's *Distoma crassum,* the opinion of Prof. J. Leidy (who so well describes the parasites) to the contrary notwithstanding. In the forthcoming issue of the *Journal of the Linnean Society* there will be a description of two more instances of the occurrence of Busk's fluke in the human subject, founded on specimens obtained from a missionary and his wife who placed themselves under the professional care of Dr. George Johnson and myself. Prof. McConnell's fluke is quite distinct from all the other human and animal trematodes at present known to science, and to this extent, therefore, the case is unique.

I am, Sir, yours truly,

Harley-street, Sept. 2nd, 1875. T. SPENCER COBBOLD.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 18, 1875.

The Act relating to Public Health that has just become law is confessedly imperfect in many ways; but its provisions can now be criticised with tolerable facility by those specially interested in them—i. e., those who are directly or indirectly called upon to administer them. It is already plain that materials will soon be forthcoming to show the weak points of the Act, more especially those contained in Part 3, relating to sanitary provisions. And here at the outset it is satisfactory to know that the medical officer of health will in urban districts be strengthened in the performance of his duty under the Artisans' Dwellings Act by those clauses of the Public Health Act that relate to sewerage and drainage. The power to purchase, to make, to maintain, and to cleanse sewers is vested in the local authority; and no stream or watercourse is to be fouled by sewage. But, though five or six subsequent clauses are devoted to sewage disposal, the whole question is still in cloudland, and we must wait for the report of Mr. Clare Read and his colleagues with a subdued hope that it will help us out of the great difficulty. The clauses that relate to privies, waterclosets, &c., ought to be sufficient if stringently acted upon; and we may recommend to the attention of urban sanitary authorities the important power given them as to providing urinals, closets, and ashpits for public accommodation. As regards removal of filth on the certificate of the sanitary inspector, no power is given, as in former Acts, to destroy as well as remove. This is a serious omission, for many filthy things require to be destroyed, inasmuch as it is not just to remove them from one district into another. The clauses relating to water-supply must be classed, like those referring to disposal of sewage, as tentative only, for both must be materially altered in accordance with the Rivers Pollution and other water Bills that may possibly become law during the next session of Parliament. But Clause 64, vesting the care of public cisterns, pumps, wells, &c. in the local authority, and Clause 70, giving power to the local authority to close polluted wells, public or private, are both most useful provisions, and calculated to aid practically in the prevention of zymotic disease. Clauses 71 to 90 inclusive, which relate to lodging-houses, should, in many cases, aid the medical officer of health in his duty under the Artisans' Dwellings Act, and ought, as one practical outcome, to result in the total abolition of all cellar dwellings. In the important clauses grouped under the head "nuisances," the law is simplified, in that a penalty may be levied in a summary way for neglect of the order to deal with a nuisance, and is amplified usefully, in that power is given to the local authority to proceed against a nuisance existing in an adjoining district. Ships are specially included as houses under this section, and training-ships are by a slight verbal change brought generally under the provisions of the Act, having been up to the present time exempt as "belonging to Her Majesty's Government." Offensive trades are specially dealt with, and much of the value of these clauses is, as we believe, due to energetic action taken by the Society of Medical Officers of Health, as also those relating to unsound food exposed for public sale. There are three clauses relating to mortuaries, which are rendered of little or no value because the erection of these places is not made compulsory. Mortuaries should be established in all urban districts. The seven clauses relating to the "prevention of epidemic diseases" are for the most part a summary or copy of the Diseases Prevention Act, and give, as is known, very great powers to the Local Government Board in the event of the outbreak of any "epidemic, endemic, or infectious disease."

Our readers are well aware that the clauses (fourteen in number) relating to infectious diseases and hospitals have already been criticised in the daily journals by both lay and professional persons. The provisions relating to conveyance of sick, maintenance of ambulances, destruction or disinfection of clothing, infected lodging-houses, and infected persons brought by ships, are all good enough, though they may not be sufficient to meet all emergencies. But the clauses above indicated are utterly spoiled in practical working, because no obligation exists on the local authority to provide hospital accommodation. They may or may not, and, as a matter of fact, in the vast majority of cases they do not, provide it, and apparently have no intention of doing so, unless compelled by law, or unless thoroughly alarmed by a formidable epidemic, and, as the consequence, a huge mortality. We do not care to discuss the various plans that have been proposed by different persons as to the best means of isolating infection. The object of this critical summary is merely to show some of the existing defects of the Act; and until these hospital clauses are rectified, we may look in vain for success in any solitary, combined, or systematic efforts, official or unofficial, to stamp out epidemic disease when once fairly introduced into a district.

It is not necessary to refer again to the provisions of the Act that give power to the Local Government Board to combine districts for the election of a medical officer of health, for the subject was very freely discussed in these columns in February last. The existing districts must necessarily be rearranged in a short time, and it is probable that a Select Committee will be appointed to consider the best principle to be adopted in dealing with this important subject.

The attention of sanitary officers should be called to certain schedules at the end of the Act, which include forms of orders &c. to be used in the ordinary course of work.

And here, for the present, we leave the Public Health Act.

Sir Robert Christison's defence of "the present system" at Edinburgh was thorough. It was conceived in the bold "no surrender" spirit. Not a lecture in the curriculum must be given up, and not one board of the famous nineteen that compete for the honour of licensing the candidate for practice can be dispensed with. Sir Robert's vision of the future, if "some vigorous reformers in the South" accomplish their projects, is something dreadful to contemplate. The prospect he drew may well scare—as it was meant to scare—all believers in the One-portal system, or even in that mild form of it, the Conjoint Board Scheme. The lions in the way are legion. It will be costly to the candidates; in addition to the cost of simple examination there will be the cost of 900 candidates travelling to London, and waiting their turn for examination; it will be absurdly unjust to university candidates; it will be a fountain of mediocrity "in all things medical—in education, in professional qualifications, and in scientific advancement";—the corporations may find their very *raison d'être* questioned; and, worst of all, the luckless examiners that may be called into laborious employment under the scheme described will find the work too much for the brain, and probably half of them will be landed in a lunatic asylum! This is the way in which Sir ROBERT CHRISTISON "lifted his warning voice" in Edinburgh against proposals for simplifying the system by which medical students are licensed to act as general practitioners in this country. It is fine to see the perfect satisfaction with which a youthful veteran like Sir ROBERT can survey "the present system," though rather painful to notice his fear of change.

As we were not convinced by Sir ROBERT's able address that there is anything absolutely and certainly right in a system which inflicts 140 or 150 lectures in one subject on a student, and 140 or 150 others upon other subjects, respectively, in the course of a winter session, so we are still unconvinced of the propriety of a system which leaves nineteen bodies to compete in the work of examining students for the purpose of licensing them to practise half their profession.

There are two points in the demand for a One-portal system which this journal has made for forty years, and which we mean to make till it is conceded. The first point is, that a diploma should be a complete instrument—not one-sided, not surgical only or medical only, but a complete licence to practise in every branch of the great art of medicine. The other is, that the body or bodies granting such a diploma should be above all commercial feelings—such as those of dependence on the fees of those whom they examine, of rivalry with other bodies doing the same work, &c. As regards the first point, we maintain that Sir ROBERT CHRISTISON himself is on our side. Here are his wise words:—

> "One condition, however, must be admitted to be indispensable. As every physician ought to be educated in Surgery and every surgeon in Physic, so every board which singly qualifies a man for registration must possess the power and the means of examining on all required subjects, medical and surgical."

Here is an admission of the necessity of examining men all round. Sir ROBERT CHRISTISON says that every board must possess the power of examining on all subjects; by which, we presume, he means that they either possess or must make themselves possessors of this power of testing a man all round. But here comes the absurd thing, that while, under the sheer force of public opinion, all the bodies but one or two examine a man completely—that is, both in Medicine and in Surgery,—they do not more than half license him, except the London College of Physicians, which gives a complete diploma to its licentiates. After Sir ROBERT CHRISTISON has admitted the necessity of every board making its examination complete, why does he not make the further admission, logically involved in his first, that the diploma which it gives should be also complete? Why should a man who is examined in Medicine by the examiners appointed for the purpose by the Royal College of Surgeons of England have no power of recovery in medical cases, while a man who has been examined in Surgery by the College of Physicians of London can recover in surgical cases? We should be most glad to have Sir ROBERT's answer to these questions. The whole system of one-sided diplomas is now out of date. Distinguished members of the College of Physicians do not think it beneath them to perform tracheotomy, and consulting surgeons do not disdain to use a stethoscope. For general practice general powers are still more indispensable. But they are not given in the single diploma of any body except that of the College of Physicians of London. This is the "present system" which Sir ROBERT CHRISTISON defends, and under which two-fifths of the men who register are only half qualified. It may continue by reason of the apathy of Parliament in such technical matters; but it is obviously unreasonable and out of date.

As to the other point, that a reduction in the number of licensing bodies is desirable, it is so generally admitted that we shall spend little time in refuting Sir ROBERT's objections, which seem to us strained and far-fetched. He and Mr. LYON PLAYFAIR probably fancy that they have changed public opinion on this point. But they have not. It is true that many of the existing bodies do their work tolerably well, though nobody would deny that they let through a good deal of "mediocrity." One board in each division of the kingdom would do the work equally well, and probably better. True, inspectors can be found to inspect nineteen bodies; but last year this inspection cost £500. Moreover, if it is possible to inspect nineteen bodies, the inspection of three might be much more thorough, in which case the boards, instead of being fountains of mediocrity, would be fountains of higher efficiency. As to the elaborate calculations by which Professor CHRISTISON shows the costliness of a One-portal system, we have to say only this—that the double diploma is to be had in Edinburgh for £16 and at the London College of Physicians for £15; and that there is ample material in the three metropolitan cities for three examining boards, without any such tax on the brains of the examiners as would send half of them to asylums. We have never believed much in Conjoint Schemes; but we believe in the One-portal system, as simple, just, uncostly, capable of being supervised, and sure one day to receive the sanction of the Legislature.

◆

THE medical profession in Ireland have reason to feel aggrieved and insulted at the very scanty remuneration which the Local Government Board has provided for the medical officers of health to be appointed under the Irish Public Health Act of 1874. Dr. O'LEARY, M.P., brought the subject before the House at the close of the session, and it is to be hoped that Government will at once see that sufficient remuneration is provided in order to secure efficient and responsible officers of health. By the terms of the recent Act it was made obligatory on the medical officer of the dispensary district to undertake its sanitary duties, the question of additional salary being left to the guardians. However, to prevent these from exercising any unwonted generosity, the Local Government Board has fixed a maximum for the increased salary, which in no case is to exceed £26 per annum! To do the guardians justice, they have, however, as yet shown no inclination to trench on this maximum, and have fixed the additional remuneration at an average of £10 per annum. The work to be done for this sum is immense, and not always free from danger. Take, for instance, Dunmore. Here the medical officer has a district containing a population of 8000 and an area of 30,000 acres. The officer of health has sent in 108 reports of 186 inspections; for this, and the time spent in giving evidence in Court when necessary, he receives the munificent sum of £10 per annum. Should he wish to resign such responsible and arduous duties, he will also be called upon to resign his appointment of dispensary officer. At Drogheda, for issuing 150 special reports on 230 cases of nuisances £20 is granted. Those medical officers of health in England who have Irish rookeries in their districts can readily sympathise with their brethren in Ireland, and understand the class of people they have to deal with. We learn from the *Dublin Daily Express* that only a few weeks since, in the county of Galway, "after the successful prosecution of an uncleanly cottager, the dispensary doctor was obliged to seek the protection of the magistrates, as the indignant delinquent had threatened the doctor's life should he again pass by his road." A common bricklayer's assistant would decline to undertake the inspection of drains, sewers, pumps, &c., let alone the other duties, even at the hitherto not approached maximum fixed by Government, of 1*s.* 7½*d.* a day. We are not surprised, therefore, to find that members of our patient profession begin to resent having such duties forced on them, and being compelled to perform them at the rate of 6½*d.* per day. A firm and manly protest against such treatment should proceed unanimously from the dispensary medical officers, and, if judiciously urged and worded, we are sure they would secure the attention and sympathy of the public; nor do we believe the Government could resist their just plea for more liberal treatment. It is stated that in England the allowance to medical officers of health for the same amount of work is double the maximum granted by Government for those in Ireland. We see no reason for this inequality, and we claim for our less fortunate Irish brethren the same scale as received by ourselves; and even then both would be underpaid for the important services rendered by them to the community.

It is somewhat appalling to learn that the prisoner in the Norwood poisoning case had in his possession three or four ounces of liquor strychniæ, and that up to this time the police have utterly failed to find out where it was obtained. Such a fact implies a serious defect either in the police system or in the state of the law, which it is to be hoped will receive illustration at the approaching trial. The particulars of the sale of poisons — such as opium, chloral, &c.—to non-medical persons by druggists would be a startling but instructive disclosure.

Annotations.

"Ne quid nimis."

MEDICAL CERTIFICATES IN CASES OF DEATHS FROM VIOLENCE.

A short time since a labourer in Somersetshire was knocked down by a train in a tunnel, and so injured that he died next day. By a singular succession of blunders, the body of this man was buried without any reference to the coroner, and without even the registration of the death. An inquest was subsequently held, the body having been exhumed for the purpose by order of the coroner, at which a point of some importance to the public and the medical profession was raised. It appears that the deceased was knocked down on the night of the 12th ult., but was not seen by a medical man until the next day, and died almost immediately afterwards. The medical attendant, although he had not been called in until the man was probably beyond assistance, was afterwards asked to give a certificate of the cause of death, and making no objection, certified that the man died from "injuries to the abdomen." In the ordinary course of events this certificate of the cause of death should have been delivered to the registrar of births and deaths, whose duty it would have been, on seeing that it was a death from violence, to communicate with the coroner before he registered the death or issued his certificate or notification which authorises the body to be buried. Through somebody's ignorance or negligence this medical certificate of the cause of death was, however, produced at the interment instead of the registrar's certificate, in consequence of which the officiating minister, after the burial, informed the registrar that he had buried the body of a person whose death had not been registered. In this case, in spite of so many blunders in the form of procedure, an inquest was eventually held, although it was necessary to disinter the body for the purpose, and the death was duly registered. The coroner—who, by the by, is a medical coroner—at the inquest somewhat severely criticised the medical attendant for having given a certificate of the cause of death in such a case, and we cannot but agree with the coroner when he said that if a medical attendant in the case of a death from violence takes upon himself to decide whether or not it was a case for an inquest, he usurps the functions of a coroner. When Mr. Lodge was asked to give a certificate of the cause of the death of this man who was knocked down by a train, he doubtless felt perfectly justified in certifying that the death was caused by "injuries to the abdomen"; but he was clearly not in a position either to say precisely how the injuries were caused, or whether they were the result of pure accident, gross negligence, or even suicide. These facts could only be ascertained by an inquest, and only on the improbable refusal of the coroner to hold one should this death have been registered on an ordinary certificate of the cause of death. We presume there are few members of the profession who would agree with Mr. Lodge when he stated at the inquest that he did not see why he should not give a certificate of the cause of death if a man were brought into his surgery with a bullet-wound through his head! In such a case it is not the duty of a medical man to attempt to decide whether the bullet-wound was inflicted by fair or unfair means, and it is moreover clearly his duty to refuse to give a certificate, and to order a reference to the coroner. Not only is it highly important that the medical man should take the initiative in bringing under the notice of the coroner all cases of death from violence, or even suspected violence, but it is also desirable that no certificate of the cause of death should ever be given which by any possibility could be refused acceptance by the registrar, and it would clearly have been the duty of the registrar of Brislington to have refused to register the above-mentioned certificate of Mr. Lodge without reference to the coroner.

SWIMMING.

With each recurring bathing season we expect to encounter paragraphs in our daily papers headed "Accidental Drowning," or with some such title; but it seems to us that the accidents from bathing have been unusually frequent this year. If Captain Webb's great exploit has led to many silly imitators on a small scale, and to some loss of life, it cannot be denied that his success has given an impetus to swimming, and led many to learn or practise that art. It is so easily learnt, so important and enjoyable, and so many facilities exist for acquiring it, that there is really little or no excuse for anyone being unable to accomplish it. And, to do the rising generation justice, physical education is not neglected as it once was, but youths of both sexes are now taught many things which even boys did not learn some years ago. In addition to the ordinary sea-bathing, most watering-places are furnished with good swimming baths; and, like everything that is worth learning, there is a right and a wrong way of learning to swim. Those who have begun young, and been taught regularly and systematically, will almost always surpass those who have acquired it by themselves. Happily, it is no longer considered hoydenish for a girl to learn to swim, ride, skate, and play at lawn tennis, or even cricket; and the gain in point of physique—to say nothing of the saving of physic—is great. The forcing of the intellect in the acquirement of accomplishments for which a girl might have no real taste, the confinement in overcrowded and heated school-rooms, and the absence of any exercise beyond that which arose in walking two and two in a body, by which "the young ladies" forming the school resembled a jointed animal like a serpent or alligator moving along the roadway, have given place to other and more varied occupations. We hear less now than in Sir Benjamin Brodie's time of weak spines, "hysterical joints," and the like, which the very imperfect training then in vogue had to answer for. No doubt many of those whose deaths have been recorded from accidental drowning were swimmers. Some of them, however, made little or no allowance for the strength of tide and currents; some, losing confidence, began to throw their arms up and became embarrassed in breathing by fear and struggles combined; and some were, perhaps, seized with that very popular cause of drowning—cramp. This cramp is an altogether peculiar affection. The swimmer goes down at once or rapidly—so rapidly as to lead to the belief that the diaphragm and muscles of respiration are the principal parts affected. Where people bathe in deep water, if there were a line of corks floating on the surface to show the direction of the tide, and if some boats, provided with steps and life-buoys, were always present, we think some of this loss of life would be averted.

CONTRADICTORY OPINIONS.

A few days ago a mother was summoned before the magistrate of the Clerkenwell Police-court for hiring a cab at the St. Pancras railway station to convey her child to the Fever Hospital, Liverpool-road. At first sight this appears to have been an offence of the greatest gravity. The surgeon at the hospital ordered the child into the hospital and the cab was disinfected. It seems, however, that the mother possessed a certificate signed by a surgeon at Belpore, where the child had been lying ill with scarlet fever, to the effect that it was "free from infection." The inspector who brought the complaint before the court is said to have expressed an opinion that the certificate was correct. The hospital surgeon differed, no doubt respectfully, from the surgeon at Belpore, who, it appears, had attended other children at the school where this one had been attacked, and the inspector, while he lodged the complaint, supported the certificate produced for the defence. Altogether there was so much contradictory evidence in the case that the magistrate dismissed it, and of course refused costs. It is much to be regretted that conflicting statements as to the danger of contagion should be promulgated by medical men. It is possible that the little boy when taken to the Fever Hospital presented symptoms which were not apparent when the surgeon by whom he had been treated at Belpore gave his certificate. But then, why was he taken to the hospital? The mother seems to have taken her son direct from the railway station to the hospital, and to have misled the cabman by telling him to drive to Liverpool-road, instead of naming the Fever Hospital as their destination, and while doing this she professes to have acted upon the certificate afterwards produced in her defence! We confess it is not easy to see why, under the circumstances, the magistrate allowed the summons to be dismissed. The whole facts did not probably transpire in court, but enough of mystery surrounded the case to call for a full inquiry. For the credit of the surgeon at Belpore it should be known *when* and *for what purpose* he gave the certificate of health? And for the honour of the lady concerned it should be explained why she took her child to the Fever Hospital so quickly, and with such strange precaution? We should like to add another question, why did the magistrate appear to regard the Inspector of Police as a sort of umpire between the medical men whose opinions were contradictory? When doctors differ is an Inspector of Police the most fitting person to say which is right?

SCURVY IN THE MERCANTILE MARINE.

During the past fortnight no less than four British ships have been reported with cases of scurvy on board. The brigantine *Cecilia* arrived in London from Lagos with two cases of the disease, and the medical inspector of the Board of Trade having discovered that the crew were not sufficiently provided with lime-juice, the captain was prosecuted and heavily fined on three counts under the Merchant Shipping Acts of 1854 and 1867. A large ship arrived in the Millwall Docks on the 6th inst., from Akyab, after a long voyage, with several cases of scurvy. The men are now under treatment in the Seamen's Hospital, and as an official inquiry as to the ship is proceeding, it would not be proper to prejudge the case. It is reported that nearly all the crew are more or less affected.

Most of our readers have seen paragraphs in the daily journals relative to two vessels recently arrived at San Francisco, and described as partly decimated by scurvy. It is futile to comment upon these apparently disgraceful circumstances until the facts are before us, but it is almost impossible to conceive that in a British ship, belonging to one of the largest owners in the kingdom, twelve men can have died and twenty-two been disabled from this eminently preventable disease. Be this as it may, it is the duty of the Board of Trade to watch the arrival home of the *Bremen*, and institute immediately afterwards, under the 14th section of the Merchant Shipping Act of 1854, a strict and exhaustive investigation into the circumstances. It is the more important that this line of action should be adopted and carried out in its integrity, because we have been lately congratulating ourselves on the decrease of scurvy in the mercantile marine. Last year only eighteen cases of scurvy were received into the Seamen's Hospital at Greenwich, as compared with an average of one hundred cases annually before the Duke of Richmond's Act came into operation. And, moreover, the facts above recorded may very properly be presented for consideration to gentlemen with ultra-Plimsollian tendencies who think that, if the ship is safe and seaworthy, it matters not as to the quality of her vital material. Good ships as well as bad ships are sent to the bottom, the latter because they are rotten, and the former because they are manned by men either rotten when they ship or made rotten by improper food and accommodation. This may be an unsavoury setting forth of facts, but the facts are reliable, and we may well wonder why, for the sake of saving a few shillings, owners and masters of ships decline to take the legislative means provided for ensuring to themselves a sound and healthy crew at starting. When the start is effected under such circumstances, the master must, in these days of preserved provisions, good antiscorbutics, and comparatively short passages, be very clumsy or very parsimonious if he cannot keep his men in fair working order, accidents and emergencies excepted.

GREAT EXPECTATIONS.

PUBLIC attention is for the moment strongly directed to the powers and functions of officers of health. This is only natural considering the prominent part which these gentlemen will have to play in the working of the new sanitary Acts. Nevertheless the notions which prevail are confused and contradictory. It may be well that some of them should be corrected. An organ which speaks of "appointments as parish or district doctors" as "plums" is not entitled to much weight. It must by this time be pretty well understood that the service of the Poor-law Board, as it used to be called, is not sought for the sake of its emoluments. As a rule these fall rather below the total of expenditure entailed by the duties imposed. It is well known that local practitioners generally take parochial or district offices because some medical man resident in the locality must be appointed, and the locality will not maintain a new-comer. It is no doubt true that "now the medical officer of health is master of the situation." Broadly, this assertion covers the case fairly enough, and we must accept the full measure of responsibility which the position entails. But it is startling to be told that "the pay is often good, and the work not over laborious." The acknowledgment that "the duties are large and vexatious, and the responsibility great," is more to the point, and better in respect of accuracy. The vexatious character of the obligations which now devolve upon the medical officer cannot be disguised. He is between two perils. If he leans towards the "local authority," which, as a rule, is chiefly concerned to keep down the local expenditure, he will probably neglect his duties. If, on the other hand, he exhibits a reasonable amount of zeal in the discharge of his functions, he is almost sure to run counter to the prejudices of his *employers*—the term is unfortunate, but it alone adequately expresses the position in which the relations are left—and they will have their revenge. It is most important that the public should realise the difficulties which beset officers of health. It is no less necessary that medical officers should clearly understand how much is required of them. It will be better to err on the side of doing too much than too little. At the same time officers will do wisely not to incur a risk of rebuff and discredit. They will most readily and successfully avoid the perils that surround them by remembering that, as a matter of fact, every "representation," although addressed in the first instance to the "local authority," is actually to be judged by the "confirming authority." Public opinion, as distinguished from local prejudice, will support the medical officer in the discharge of his duty, and if his representations can be successfully maintained before the Secretary of State or the Local Government Board he has really nothing to fear. The largest anticipations are cherished, and we believe they will be justified by the diligence and discretion with which officers of health will discharge their onerous duties. A single eye to the *public* interest will ensure success. Meanwhile the community at large will do well to bear in mind that without public support the medical officer must be practically powerless, and in too many instances probably he will fall a victim to his own enterprise.

THE WORCESTER INFIRMARY.

THE Executive Committee of the Worcester Infirmary still stands on its dignity, and refuses to make any alteration in the rule which has lately occasioned, and very reasonably occasioned, the resignation of the senior physician, Dr. Inglis. It does not augur well for the peace and welfare of a hospital when its honorary medical staff and its executive committee are at such variance that the medical staff can get no redress from the executive committee, and is compelled to appeal to the general body of governors. But this is the state of things in the Worcester Infirmary; and all because the Executive Committee will not agree to a slight alteration in the rules, to the effect that when an honorary officer cannot attend he shall try to secure the attendance of a colleague, and, failing this, the house-surgeon shall see the patients. More is conceded by the medical staff—namely, that when they cannot keep their infirmary engagements the particular reasons for their absence should be stated to the committee. It seems to us that these might have been taken for granted by the committee, unless absence became so frequent as to require explanation. We are not aware that explanations are demanded by the committee of any other hospital. We can only hope that the body of governors will more generously recognise the consideration due to busy practitioners who do their best to harmonise the claims of private practice and hospital duties.

YORKSHIRE VARIOLOPHILISTS.

GOOD service is being done to the cause of vaccination by some of its shortsighted or misguided opponents, who in some parts of Yorkshire have been able to enlist official influence on their side. Popular appreciation of the value of a great movement, which has for its object the prevention of disease, is apt to become languid unless kept alive by some obstruction, which, releasing from the influence of the reform a certain area, leaves the contrast distinct and conspicuous. Our readers are aware that certain towns in the West Riding of Yorkshire have proscribed vaccination, and afforded thereby an illustration of its value. The small towns of Keighley and Dewsbury have furnished 59 of the 348 deaths from small-pox which occurred in England and Wales during the second quarter of the present year, in Keighley no less than 47 deaths out of 404 being due to that disease. For most of these deaths the guardians of Keighley are morally accountable, and that they are not also legally responsible for them is only an instance of the imperfect way in which sanitary obligations are enforced in this country. The opponents of vaccination have found an advocate, of the usual character, in a member of the Leeds Town Council, who has made serious public charges against the medical officers of the Leeds Small-pox Hospital, of wilful inaccuracy in their reports. The chief part of the charges was so devoid of even the shadow of foundation, as to have been unable to bear repetition. They resolved themselves into an allegation of inaccurate returns concerning 8 out of 720 cases. To these the surgeons to the hospital, Mr. F. Hall and Mr. Libbey, were able to return a conclusive reply, which must have opened the eyes of some of the supporters of the anti-vaccination movement, as far as any opening of such eyes was possible, to the unfounded character of the statements on which their opinion was formed. The *Leeds Mercury* sums up the dispute in a very sensible article, which urges justly the need for some reparation to the surgeons whose character has been thus attacked. Their system of ascertaining the facts of the cases under their care is only liable to error from over-conscientiousness, an endeavour to do honest justice to the question, and their conclusions illustrate the familiar facts concerning the effect of perfect and imperfect vaccination in a very forcible manner.

UNJUST CENSURE OF MEDICAL MEN BY JURIES.

SOME people hold very curious views as to the binding duty of doctors to be ready at a moment's notice in the middle of the night to go anywhere and to anybody. A medical man may be ill, or he may have other cases as binding as the one to which he is called—but he must go; he must do incompatible duties, he must perform impossibilities, he must be in two places at once, he must take no account of the limitation of his own but human strength. Which of us has not been called, exhausted after a day's work or out of a heavy sleep, to do terrible duties, which we would have given five pounds to escape, and for doing which we have received neither thanks nor a fee. Unfortunately there are no coroner's inquests to investigate the neglects of ungrateful patients. But once let a doctor fail in ubiquity, or a patient die without seeing a medical man, and then comes the coroner's inquest, and the chances are that everybody will escape but the doctor who never saw the patient, and who is presumably least to blame for his death. These remarks are called forth by an inquest at Specton, near Hull, on the body of a harvester who died in the stable of his employer, Mr. Wilson, after several days of illness, during which it is not pretended that any advice was sought for him. When he got very ill, too ill to leave the premises, Mr. Wilson sent his groom for a doctor—not his own doctor. The first doctor applied to (Dr. Dawson, of Hunmanby) was engaged with a midwifery case; the second (Dr. Denton) was in a state of temporary exhaustion after an exceedingly hard day's work, requiring him at last to transfer a professional engagement to a friend. Being told that the patient was suffering from diarrhœa, he sent a mixture, and promised to go in the morning. Shortly after the groom returned the poor man died. Then came the easy inquest. No post-mortem examination was made; no medical evidence was asked, though the written opinion of Dr. Denton as to the probable cause of death was accepted as the basis of a verdict. The two doctors were freely censured by the jury, the coroner concurring. This was the more easy as they were absent, and had not the slightest idea that an inquest was being held till they saw the fact and the censure upon themselves in the paper. Their defence is ample, so ample that the jury must have directed their censure to other quarters if the usual English course had been followed, giving men whose conduct is blamed an opportunity of explaining it.

We have particulars of another case essentially similar, reported to us from Middlesborough, in which Mr. Henderson, of Middlesborough, was censured by a jury for not visiting a club patient while he was in attendance on a case of labour. Here, too, the coroner and the jury were unfair enough to do the easy business of censure in the absence of the medical man. This evil is really too bad and too common to be much longer tolerated, and we should advise medical men affected by it to make complaint to the Lord Chancellor.

NEW ACID FOUND IN THE URINE AFTER INGESTION OF CHLORAL HYDRATE.

MUSCULUS and De Merme have recently published, in the *Comptes Rendus*, an account of a curious acid which seems to be formed under the above conditions. Examining the urine of persons who were taking sixty to eighty grains of chloral hydrate per diem, they found it strongly acid, reducing copper solutions and rotating polarised light to the left. The acid is thrown down by basic lead acetate, and forms stellate crystals like those of tyrosine. It is a powerful acid, decomposing carbonates with effervescence, while its salts are unaffected by acetic acid. It is very soluble in water and alcohol, but not in ether, and reduces salts of copper, silver, and bismuth, and decolorises sulphate of indigo. It is said to contain 31·60 C, 4·36 H, and 26·7 Ch. All its salts are soluble in water except the basic lead salt, but insoluble in absolute alcohol. The discoverers propose to call it provisionally *urochloralic acid.* It would seem from this discovery that chloral, like benzoic acid, undergoes material change in the organism, and is excreted in a different form, though some passes unaltered. The quantity of the new acid found was from ten to twelve grammes per litre of urine.

ROYALTY AND TEMPERANCE.

THE gratifying announcement that Her Majesty the Queen would become a patron of the Church of England Temperance Society is followed up by the almost equally gratifying statement that the Rev. Basil Wilberforce has received a letter announcing that his Royal Highness Prince Leopold will become President of the Oxford Branch of the Church of England Temperance Society. The Church of England can do no higher service to this country than by enlisting the sympathy of Royalty and rank in the temperance movement. It is high time that the amount of drinking which goes on, not only in Liverpool, but in all parts of the kingdom, should be abated, as something intensely degrading and disgraceful, having no foundation in either sense or morality, as it certainly has none in physiology. Let us hope that we are at the beginning of a great religious and patriotic effort to increase the temperance of every section of the community. Mere patronage will not do it. But we shall have more assistance in this enterprise from the Royal Family than is implied in mere patronage; and not the least glory of the Victorian reign will be the perception of a great social vice by Her Majesty, and the desire personally to help in its removal.

TREATMENT OF HYDATID DISEASE OF THE LIVER.

THE prevalent belief that simple tapping of a hydatid cyst in the liver is sufficient for its radical cure, owing to the death of the echinococcus following the escape of its fluid contents, is not entertained by M. Verneuil, the eminent surgeon attached to the Hôpital de la Pitié (*Revue de Thérapeutique Medico-Chirurgicale*, August 15th). He believes that the remains of the cyst acting as a foreign body, if they do not suppurate themselves, yet set up suppuration in their vicinity. Recognising also the danger of peritonitis from escape of the hydatid fluid into the abdominal cavity, he does not adopt the so-called method of Recamier—viz., external application of caustic—nor other means of promoting adhesion; but he begins by puncturing the most prominent part of the cyst with a large trocar and canula. He then introduces through the canula a large gum-elastic catheter. Adhesions take place between the visceral and parietal peritoneum, and, there being constant means of escape, there is no retention of the fluid. Repeated injections of disinfectants, as solutions of carbolic acid or alcohol, are made into the cyst, the walls of which are thus allowed to slowly contract.

THE PREMIER IN A COLLISION.

The Prime Minister has been in a railway "accident," and, we are happy to be informed, has escaped without injury. The train in which he was travelling came into collision with an engine standing on the rails at a station, and, although the shock was severe, it is said Mr. Disraeli "never raised his eyes from the newspaper he was reading." It is not explained whether this is to be taken as a proof of the Premier's self-possession or of the absorbing character of the article he chanced to be reading. It might be interesting to learn the name of the paper and the nature of the piece of literature which proved so engrossing. At the same time it must not be supposed that the behaviour of Mr. Disraeli, taken by itself, was really so extraordinary as it may appear. A shock may for the moment deprive its victim of the power of movement, and, as a matter of fact, it is exceedingly likely to produce that effect. It does not follow, however, that no worse consequences can ensue from an occurrence of this class. The concussion may be momentary in its effects as it is instantaneous in its production, or it may have a double phase: the first part a mere shaking, like thoughtless nurses inflict on children when with a rough jerk they "quiet" them in the midst of a crying fit; the second, a concussion of the brain or spinal cord within the cranium or vertebral column, which leaves some injury—perhaps small, possibly severe—to the delicate organism so rudely shaken. It is of moment, in the interest of medical truth, that it should be widely understood how dangerous these shakings actually are, and how disproportionate to their immediate effects may be their remote consequences. The circumstance that a traveller is not startled by a collision in which he happens to be included determines nothing as to the result. He may even sleep through the "accident," and yet afterwards suffer evil consequences. We trust Mr. Disraeli has escaped; but it must not be assumed that everybody who exhibits unmoved composure in an accident is uninjured.

BURIAL OF STILL-BORN CHILDREN.

Although the provisions of the Birth and Death Registration Act, 1874, fell short of what was desired by those who wished to secure the strongest precautions against the burial of deceased children as still-born, it is satisfactory to find that cemetery authorities are careful to see these provisions duly carried out. Under this Act, a person who has "control over, or who ordinarily buries bodies in a burial-ground," incurs a penalty of ten pounds by permitting the burial of any deceased child as if still-born. A like penalty is incurred if the body of a still-born child is buried without the production of one or other of three formal documents: either a written *certificate* that the child was still-born, signed by a registered medical practitioner who was in attendance at birth or who has examined the body; or a *declaration* signed by a person qualified according to the Act to give information of the birth, stating that no registered medical practitioner was present at the birth, or that his certificate cannot be obtained, and that the child was not born alive; or, an *order* from the coroner in cases where an inquest has been held. An undertaker recently applied to one of the London magistrates for advice under the following circumstances:—He had taken the body of a still-born child from the Westminster Hospital to the Brompton Cemetery, with a certificate from one of the hospital staff, whose name not appearing in the Medical Register, the cemetery authorities refused to accept the certificate. As these certificates can only be signed by registered practitioners who have been present at the birth, or who have examined the body, it is necessary, in all cases where such a certificate is not forthcoming, to obtain and produce to the burial-ground authorities a declaration of the facts of the case (a form for which may be obtained from the local registrar), signed by the father or mother, or other person qualified to give information of the birth, including any person present at the birth. The provisions now in force, if strictly carried out, will doubtless check to a considerable extent the dangerous facilities which previously existed for burying deceased children as still-born; they err, however, rather on the side of laxity than on that of interposing any unnecessary obstacle in the way of the interment of still-born children. It is desirable that the comparatively new law on the subject should be more widely known and more thoroughly understood.

ABSORPTIVE POWER OF THE SKIN.

A. von Wolkenstein has recently made some experiments on the skin of frogs, kittens, rabbits, and mice. He divided the skin at the upper part of the thigh, and then withdrew it over the toes; the sac thus formed was filled with distilled water, and immersed in test solutions of various salts. The results obtained were:—1. The skin is permeable to watery solutions, but not for concentrated solutions. 2. Increased temperature augments the absorptive capacity of the skin; in fact, absorption stands in direct relation to the temperature of the fluid. 3. In young animals the skin absorbs better than in old ones. 4. The presence of hair and wool diminishes absorption. 5. Some alkaloids likewise undergo absorption through the skin, and toxic phenomena can be thus induced. The skin of dead aborted fœtuses of the above animals is only permeable at a high temperature.

UNINQUIRING INQUESTS.

When a man, lately left in comparative health, is found dying, with a bottle of prussic acid at his side, his friends cannot complain of a verdict like the following: "That the deceased died suddenly, but from what cause there is not sufficient evidence to prove." This kind of inquest and verdict are reported in the case of Henry Staffell, aged seventy-three, of Glastonbury. The coroner, Dr. Wybrants, did not order a post-mortem, on the ground that he considered it would be of little use. We regret that such a course should have been followed by a medical coroner. The odour of the acid might have been looked for. Its absence would have gone far to remove the public impression that will be left by the doctor's evidence, that in his opinion the deceased had taken some of the acid, though the odour of it was obscured by recent smoking. The presence of it would, of course, have confirmed this impression. As the object of inquests is to give precision to the record of the cause of death in doubtful cases, a post-mortem should not be omitted, especially by a medical coroner.

THERAPEUTIC PROPERTIES OF SALICYLIC ACID.

Some very important observations by M. Wagner on salicylic acid appear in a recent number of the *Journal für Pracktische Chemie*. His results are thus summarised by Dr. Stevenson in the August number of the *Journal* of the Chemical Society:—(1) Salicylic acid is superior to phenol (carbolic acid) as a disinfectant for fresh wounds and old sores. (2) A disinfecting action is insufficient for venereal sores, and corrosion is requisite. (3) In eczema of the head and face, with discharge, salicylic acid is extraordinarily efficacious, presumably because it quickly destroys the contagium. (4) In all cases where fermentative changes occur in the contents of the alimentary canal salicylic acid acts more efficaciously than other antiseptic substances, since it can be administered in larger doses. (5) Its use is highly promising as a prophylactic in all diseases in which it is believed that the morbid processes are connected with microscopic organisms. In diphtheria, not only is salicylic acid a powerful restorative remedy, but it also appears to shorten the course of the disease.

THE PRESYSTOLIC MURMUR AND THE CARDIOGRAPH.

IN an article on the Presystolic Murmur in our issue of September 4th (p. 351), we regret to find that we overlooked the researches of Dr. Mahomed, who has devoted so much time to the exposition of the clinical worth of the sphygmograph. From a letter we have received from Dr. Mahomed, it appears that he anticipated by nearly three years the results obtained by Dr. Galabin in the application of the cardiograph to demonstrate the auricular systole in cases of mitral stenosis. The account of his researches is to be found in his paper on the "Physiology and Clinical Use of the Sphygmograph" (*Med. Times and Gaz.*, vol. i., 1872, pp. 427 and 509), where are given "several cardiographic tracings in cases of mitral contraction, which exactly correspond with those since published by Dr. Galabin." He further adds that "in paper No. 6, pp. 569 and 570, you will find that I have especially pointed out how completely they refute Dr. Barclay's theory." We hasten to bestow honour where honour is due, and regret that Dr. Mahomed's labours should have received no acknowledgment in the article referred to.

THE LATE DR. FREDK. W. HEADLAND.

WE have to record the death of the late Dr. F. W. Headland, at the early age of forty-six. His health broke down about two years ago, and since that time he has lived in seclusion. Dr. Headland distinguished himself as an undergraduate of the University of London, and obtained some of the highest honours in that institution. He was a Master of Arts and Doctor of Medicine of the University of London, and a Fellow of the College of Physicians at the time of his retirement from the profession in 1874. Dr. Headland was senior physician to Charing-cross Hospital, and was well known in the profession both at home and abroad by his work on the Action of Medicines in the System, for which he was awarded the Fothergillian Gold Medal by the Medical Society of London in 1852. He was the author of Lettsomian Lectures on Materia Medica, and of several lectures and papers on subjects of practical medicine, published in THE LANCET.

Although his manner was retiring, Dr. Headland was greatly esteemed by his professional brethren and by those friends with whom he was intimate. In his professional relations he was guided by a high sense of honour and probity.

WILLAN AND BATEMAN.

WE understand that the "Delineations of Cutaneous Diseases" of these two authors, which at one time enjoyed such great popularity, is about to appear in an improved edition; or rather Willan's book is to form the basis of an atlas after having been remodeled so as to represent the dermatology of the present day, and at the hands of Dr. Tilbury Fox. The work will consist of eighteen monthly parts of four plates each, and half of the seventy-two plates will, according to a prospectus in our hands, be new. Willan and Bateman were two able workers of whom English medical science has much reason to be proud, for they undoubtedly "succeeded in reducing for the first time the leading facts of dermatology from a state of comparative confusion into a simple, systematic, and easily comprehended arrangement," and it is so far satisfactory that their chief classical publication is likely, in its improved form, to be available for scientific purposes.

QUEEN'S COLLEGE, CORK.

THE chair of Materia Medica at the above-named College is now vacant. Dr. Macnaughton Jones, who has for many years been identified with tutorial departments of the College, is, we believe, a candidate. Those who have had opportunities of observing the manner in which Dr. Jones always engaged the attention and interest of his pupils must feel that if he be elected he will succeed in making his lectures on Materia Medica and Therapeutics as interesting and profitable as his lectures on Anatomy.

A CLERICAL ERROR.

WE regret that, owing to an unfortunate clerical error, the town of Huddersfield was on the 4th inst. reported by us to be suffering from an outbreak of scarlet fever. It ought to have been printed Hurdsfield instead of Huddersfield. The outbreak in question occurred in the Hurdsfield portion of the borough of Macclesfield. It was the vicar of Hurdsfield —not the vicar of Huddersfield—who refused to close his school when requested to do so by the sanitary authority. We are glad to state that since the school in question has been closed, on the recommendation of the Lords of the Education Department, the epidemic, which at one time threatened to be severe, has considerably abated.

IT is satisfactory to receive information of some improvement, however slight, in the sanitary condition of Simla—a locality on the hills that may be termed the health-resort of India, but which would seem to require an energetic medical officer of health. Thither sick officers and civil servants are sent to regain their bodily vigour; no effort should therefore be spared to enhance the natural salubrity of Simla. According to the Indian correspondent of *The Times*, the cholera epidemic is disappearing, after having caused nearly two hundred deaths, of which number, be it observed, only eight or ten were Europeans. How much remains to be done will be seen when we state that the night-soil is buried in trenches a few hundred feet below the most populous part of the station, and when the wind blows up the hills the stench is intolerable. The drinking-water is said to present occasionally the appearance of milk. The correspondent hopes that the warning of this year will be taken to heart, and that we shall hear no more of cholera at Simla.

THE *Times of India* comments upon Dr. Blanc's report on the last outbreak of cholera in the Yerrowda Gaol, which is stated to be a very interesting contribution to the medical history of the disease. The investigation would seem to establish the conclusion that cholera poison is communicated through water. The Sanitary Commissioner for the district in which the prison is situated insists that the practical lesson to be learnt from the outbreak is the great danger of allowing persons (as is so commonly the case throughout India) to drink water from a river which has been polluted by "dhobies" washing dirty clothes in it, and by other impurities.

The Commission appointed to inquire into the working of the Factory and Workshops Acts concluded its sittings at Glasgow last Saturday. A good deal of valuable information was given by members of the profession. Among others examined was Dr. Eben. Watson, who expressed his belief, judging from the great number of cases of deficient development in children, that there is a deterioration in the physical condition of the factory population, and that if it were not for the protection of the medical examination and certificate, the race would rapidly and universally deteriorate. He thought the very fact of the surgical inspection of every young worker prevented parents from presenting weakly children. Another physician, Dr. Irvine, was of opinion that the town population would soon die out if they were not constantly recruited from the country.

An important meeting of dentists was held at Manchester lately, under the presidency of Mr. C. J. Fox, for the purpose of taking measures to improve the position of the dental profession. The following resolution was passed, "That it is desirable that a committee be formed to see what steps can be taken to arrest the continued influx into the profession of illegitimate practitioners, by the adoption of the principles of registration and compulsory education." It was also resolved to authorise the opening of a subscription list to defray the expenses of such committee in making an appeal to Parliament next session upon the subject. We are given to understand that the movement is supported by the leading dentists in London.

In consequence of the prevalence of cholera in Bangalore a cholera camp is to be established about two miles from the cantonment. All incoming trains will be overhauled by a medical officer, and such passengers as may be suffering from the disease will be detained. Other stringent sanitary regulations have been adopted, which we hope will prove successful in dealing with the outbreak.

In a report on the Royal Gardens at Kew, Dr. Hooker, referring to the attempts made to acclimatise various plants in other than their native countries, says that the prospects of ipecacuanha cultivation are far less encouraging than those of the chinchona. He recommends, however, perseverance in the cultivation of the former.

We understand that the outbreak of scarlatina among the children in the married quarters of the Royal Engineers at Chatham has subsided. As a precautionary measure, children living in the recently infected quarter will not be allowed to attend the school of the corps for some time.

In London last week 1492 deaths were registered, including 2 from small-pox, 25 from measles, 71 from scarlet fever, 5 from diphtheria, 69 from whooping-cough, 26 from different forms of fever, and 190 from diarrhœa. Different forms of violence caused 49 deaths in the period.

From Dresden we learn that a serious outbreak of trichinosis has occurred among the military stationed there. In all about 50 soldiers have been attacked. Regulations against the consumption of half-raw pork have now been issued by the authorities.

It is intended shortly to increase the accommodation for in-patients at the Royal Westminster Ophthalmic Hospital. The surgical staff have suggested an additional storey to the building. Last year 2434 operations were performed in the institution.

FOOT-AND-MOUTH DISEASE.

The contagio-infectious vesicular fever of animals, commonly known as "foot-and-mouth disease," has for some time been extending more or less rapidly over the country, and is now prevailing to an alarming and most harassing degree. For nearly forty years, when it was introduced into Britain from the Continent, it has prevailed more or less, its virulence being greater, apparently, during the warm weather, and its prevalence more notable when cattle, sheep, and pigs are moved about; indeed, its extension always coincides with the increased movement of animals.

For a long time the disease has been particularly annoying to the cattle-dealers and the agricultural community generally, and there can be no doubt whatever that it has very materially tended to increase the price of meat, not only from the depreciation it occasions in the value of the animals affected, but also from the restrictions it gives rise to on the part of the authorities, who attempt, after a fashion, to check its spread, and in doing so more or less hamper the trade in cattle.

The disease in itself is not at all a serious malady—at least, so far as the mortality from it is concerned,—and this is, perhaps, the reason why no efficient steps have been adopted to extinguish it, as the cattle-plague was extinguished. Indeed, there are few maladies to which animals are liable which require less skill and medical treatment to restore the sick to health than this. Hence we find that the columns of the daily papers teem with remedies, all of which are highly lauded, but nearly all of which are quite unnecessary—some are even hurtful—if the sick animals are properly fed and cared for.

Though so trifling as a rule, yet with young animals, as pigs, it is sometimes exceptionally destructive, and if neglected it may even be productive of much mortality among adults. What renders it a most embarrassing and costly disease is the great facility with which its contagium can be diffused by means of roads, pastures, commons, watering ponds, market and fair places, manure-carts, clothing, creatures not themselves susceptible, railway-cars, cattle-ships, and many other ways too numerous to specify here. There is also good evidence to prove that this contagium is possessed of a considerable degree of vitality, and can withstand the influence of atmospherical changes for a long time. Cattle, sheep, and pigs have also a wonderful aptitude for the reception of the virus, so that but few of those exposed to infection escape; and as the period of incubation is short, and does not vary much, we may have wide tracts of country infected in a very short time if no precautions are taken to isolate the sick and prevent conveyance of the virus. Thus it is that during the pasture or grazing season, when freer communication takes place between herds and flocks, and when strange animals bought at fairs are mixed with the home stock, we have nearly every county suffering more or less extensively, and in proportion generally to its importations, the intelligence and honesty of its cattle-owners, and the energy and knowledge brought to bear by the local authorities.

The damage it causes to fat and milch stock is very heavy, particularly at certain periods. Perhaps it could scarcely be estimated at less than three pounds for a milch cow or fat ox, and ten shillings for a sheep or pig. The pecuniary loss, therefore, becomes alarmingly high in the aggregate. A few days ago it was reported that no fewer than 3186 animals were affected in Bedfordshire; and in West Sussex, during the month of August, 3145 cattle, 7330 sheep, and 156 pigs were stated to have been attacked. In many other counties the number has not been less, and in some it is steadily increasing. The disease now prevails in England, Scotland, and Ireland; and though the returns of the numbers affected are sufficiently startling, yet they are very far from giving anything like an idea of the extent to which the malady is raging. To our knowledge, farmers and others will not report the existence of the disease if they can possibly help it, and in some counties the local authorities appear to be quite indifferent to its being either reported or checked. It must be remembered that all expenses connected with it are defrayed out of local rates and magistrates, in only too many instances, try to keep these down as much as possible, though their doing so may bring heavy loss upon the community at large.

Then the system of inspection is utterly worthless; the principal agents being the police, who, in addition to their being utterly incapable of performing the difficult task of successfully contending with contagious diseases, are undoubtedly active bearers of the contagium. Competent veterinary surgeons are rarely employed, and these merely to certify to the presence of the disease, not to trace it to its source, to discover how, where, and when it was diffused, and to carry out those sanitary measures which alone will suppress it. Indeed, the whole system is absurd in the extreme, and it is very questionable whether it does not do far more harm than it is capable of effecting good. There is no veterinary organisation to control this or other contagious diseases of animals, consequently our animal losses from them might be reckoned by millions. It is true we have a Veterinary Department of the Privy Council, but it appears to be impotent to do more than issue a few returns which, even if reliable, are of very little value.

The greatest abuses exist with regard to these maladies, the prevalence of which brings forth a class of people who trade upon the misfortunes of others. Butchers, dealers, and others, buy diseased or contaminated stock at a low price, travel it along the public highways, expose it in fairs, journey it by rail or ship, and, except in the rarest cases, without let or hindrance.

Not only is the present trifling with the malady futile, but in several ways it is very unfair and oppressive. For instance, the total absence of any uniformity in attempting to carry out the orders of the Privy Council leads not only to no useful end, but is sometimes a source of hardship, as when the local authorities in a county are very severe and stringent, and those in the surrounding counties are just as remiss. From the want of competent advisers, local authorities are also not unfrequently guilty of most unreasonable acts, which, while they may have no good result, cause nothing but annoyance and loss to individuals.

There is ample proof that Irish cattle are a fertile source of infection, and, though we are continually assured that contagious diseases are very rare in that country, yet we know that stock from it is dreaded by those who have suffered from such a malady as the foot-and-mouth disease or lung plague. The fact is that in Ireland, as in England, the police are the sanitary inspectors of animals, and though it also boasts a Veterinary Department, it is really of as little utility as that in Whitehall-place.

As for "Port" inspection, without other precautions which are not adopted, it is altogether fallacious. Thousands of animals may be, and are, passed as healthy in the very cursory examination to which they are subjected, and yet each might be an active propagator of disease. This more especially applies to Irish cattle, which, even if sound when embarked from Ireland, may nevertheless become infected on board the steamers that carry them across to this country, as these are never properly disinfected; and what between the exhaustion of the animals, the foul air, and the high temperature, we can scarcely doubt that the poison germs, lurking everywhere on board, find a ready and a congenial soil.

Lax as is the traffic between Ireland and England, it is, comparatively, excessively severe with regard to that from foreign countries; and we are certainly of opinion that, looking at the manner in which home and Irish stock is dealt with, foreign importers have much to complain of in the way of unfairness.

The fact is, that unfairness, embarrassment, heavy annual losses, higher and still higher prices for meat, and danger to our own species will be the order of the day until the public takes the matter up, and insists that these diseases shall be dealt with by a central authority, that an efficient organisation like that of Germany shall be instituted to carry out the measures devised by that authority, and that the expenses incurred be defrayed by the country. A tithe of the losses sustained every year from this disease alone would suffice to extinguish it and other animal contagions, and secure to the country valuable services besides. Until this is done it would be better to abolish the Veterinary Department of the Privy Council, and allow its measures to lapse, as they are inefficient, and only stand as a sad evidence of our national method of conducting sanitary affairs.

TOBACCO IN RELATION TO HEALTH.

DR. RICHARDSON, F.R.S., delivered a lecture on this subject before a very large audience at Birmingham on Wednesday evening, the 15th inst. The lecture was delivered in connexion with the Laws of Health class of the Midland Institute. After speaking of the introduction of tobacco to Europe, and its enormous consumption at the present time, the lecturer said: The nature of the luxury forms a subject of discussion on which the extremest views prevail. On one side tobacco has been held up as the most harmless of luxuries; and on the other side it has been denounced as the originator not only of mere functional, but of some worst forms of organic disease. Following out the researches made by himself, he showed the constituents of tobacco smoke and their results upon the human body, and pointed out the effect exerted by different kinds of tobacco. Speaking of the influence of smoking on the mental faculties, he said: When mental labour is being commenced indulgence in a pipe produces in most persons a heavy dull condition; but if mental labour be continued for a long time, until exhaustion is felt, then the resort to a pipe gives to some *habitués* a feeling of relief; it soothes, it is said, and gives new impetus to thought. This is the practical experience of almost all smokers, but few men become so habituated to the pipe as to commence well a day of physical or mental work on tobacco. Dr. Richardson carefully discussed the question whether the practice of smoking could be considered, fairly, as a cause of those fatal diseases, consumption, cancer, and apoplexy. The argument, he stated, was conclusive against this extreme view. The same conclusion was arrived at in respect to insanity, epilepsy, St. Vitus's dance, heart disease, and chronic bronchitis. At the same time, immoderate smoking cannot be carried on without danger, sometimes even to life itself.

Correspondence.

"Audi alteram partem."

WOOD v. THE MANCHESTER, SHEFFIELD, AND LINCOLNSHIRE RAILWAY COMPANY.

To the Editor of THE LANCET.

SIR,—I am unwilling to trouble you with any further remarks on this case, but trust you will allow me to make a few observations with regard to two points mentioned in Mr. Fox's letter last week, because I think they will leave a false impression of the amount of evidence offered on the part of the plaintiff, and of its credibility. And I wish to disclaim altogether the feelings of a partisan in the matter, my former letter being written rather with a desire to represent the medical features of the case impartially, and not from any wish to raise a discussion on its merits from a legal point of view. I thought the doubt which seemed to exist with regard to the state of Peyer's patches, during the different stages of a case of enteric fever, might be of interest, and that perhaps some more definite understanding might be arrived at on the subject. I am glad to find that you think this difference of opinion is worthy the attention of the profession.

Now, with regard to the amount of evidence offered in favour of the view of traumatic meningitis, will you permit me to draw your attention to the fact that it is not all contained in the report of the inquest, voluminous as it is, which was forwarded to you by Mr. Fox. I was not present at the inquest, and consequently the evidence I gave at the trial does not appear there. I was very anxious not to obtrude anything of a personal nature into my letter, but in consequence of what has fallen from Mr. Fox, I will ask you to allow me to make this short explanation.

I was present at the post-mortem examination only at the request of my partner, Mr. Lister, and should have taken no part in it but that Mr. Morris, who was making it, cut his finger soon after examining the brain, and I then finished the examination. I however watched Mr. Morris in his dissection of the brain, and very carefully noted all the appearances presented. Mr. Morris made the examination in the main exactly as it would be made in a hospital post-mortem room. I knew none of the gentlemen who were present, and had not seen the deceased during his life, and as I did not expect to be called at the inquest, what observations I made were entirely without bias. The appearance of the brain membranes was such as to leave no doubt at all in my mind that acute meningitis had been present, and the facts which I noted were briefly these:—That the arachnoid was inflamed, thickened, and covered with patches of effused lymph; that its layers were adherent, and that there was smearing of turbid serum over the brain. The pia mater was congested, the meningeal vessels turgid —some vascular injection of brain-substance; no effusion in lateral ventricles. There certainly were adhesions between the layers of arachnoid, and I am sorry that Mr. Fox should vaguely hint that when he admitted there were these several "filaments or pieces," not being "blood-vessels," between the layers of arachnoid, he was thinking of the Pacchionian glands. He did indeed attempt to prove that there might be these filaments in the healthy brain, but his friend Dr. Leech was obliged to differ from him about that, as I also believe do the numerous anatomical authorities Mr. Fox has so kindly recommended to my notice. Will you allow me also to point out another difference of some importance between Dr. Leech and Mr. Fox, who both visited the patient together during his life. Mr. Fox discovered a *rose rash*, which gradually became, on being asked particularly about it, an "ill-defined one." It was so "ill-defined" that Dr. Leech could see nothing at all of it.

With respect to the value of the evidence given by me, I have been assured, in a communication from one of the three eminent gentlemen to whom Mr. Fox submitted the evidence as given at *the inquest*, that if my evidence had been given before the coroner, he should have advised the Railway Company not to go into court at all. I therefore feel that the report of the inquest does not convey a correct impression of the relative value of the evidence given at the trial with respect to the "conflict of statements" which appears in the report. I think we none of us perhaps agreed with the *description* which Mr. Morris gave of the adhesions, since he described them as being firmer and more dense than would be the case; but for the truth of the broad facts stated by him, I can only say I had the evidence of my senses, and was in a particularly favourable position for judging correctly.

There are two questions in connexion with this case which seem to me to be the ones of chief interest. Firstly, does any recognised opinion exist with respect to the condition in which Peyer's patches would be found after death on the sixteenth day of enteric fever? Would the absence of ulceration be sufficient to exclude the existence of the fever for that length of time? Secondly, accepting as facts in a case the existence of congestion of patches and of mucous membrane, but not *ulceration*, after an acute illness of sixteen days, together with an undeniable previous history of blow on the head, and severe nervous shock, followed by headache more or less persistent till the time of the acute illness, which acute illness might point either to acute meningitis or to enteric fever, but did point to the former for some time before death, and was treated as such by the medical men in regular attendance, and that after death there was found some evidence of recent and acute inflammation of the membranes of the brain, would not the presumption be very strong that death had resulted from traumatic meningitis?—I am, Sir, your obedient servant,

Doncaster, September 6th, 1875. J. B. Withington.

SERJEANT WHEELER ON INSANITY AND FRIENDLY SOCIETIES.

To the Editor of The Lancet.

Sir,—You have done good service to the medical profession and the public by calling attention to what you aptly designate the "singular lucidity of statement" in Serjeant Wheeler's summing up and address to the jury in the recent case before him of Lovell v. Behrens, tried in the Marylebone County Court.

This may perhaps be a fitting occasion also to call attention to a judgment of that learned judge delivered in his then court at Liverpool upon the moot question, so important to the poor, whether insanity was bodily sickness, entitling the members of friendly societies to the benefit of the sick fund. The decision then given to this question has not hitherto been brought with sufficient prominence before the public, although I am glad to say that it is now published in the eighth edition of "Tidd Pratt's Law of Friendly Societies," and will doubtless be extensively read. The state of the question at the time the judgment was delivered was to this effect: that in the opinion of the late Mr. Tidd Pratt, Registrar of Friendly Societies, and other authorities, "Insanity is not to be regarded as bodily sickness, because by sickness is meant a state of bodily disease, and has no reference to lunacy, which is a derangement of the mental faculties."

The judgment of my friend Mr. Serjeant Wheeler was delivered soon after the death of my friend Mr. Tidd Pratt, and is based on physiological grounds, and in accordance with those organic laws of nature, upon a knowledge of which the stability of human laws must depend. "It is necessary," says Serjeant Wheeler, "in considering the question, to bear in mind the natural and essential relations of mind and body. Every manifestation of mind in this life is made by and through its bodily organ, the brain; and the mind is so influenced by the brain that the condition of the former is an invariable index to the constitution and condition of the latter. Hence all causes of temporary or permanent disturbance in the health of those parts of the brain that manifest the mind produce in the same degree the signs of mental derangement, and, *vice versâ*, all symptoms of mental derangement indicate a proportionate disturbance in the sanitary state of the mind's bodily organ, the brain. Some years since, when it was the habit to examine the brain with the aid only of the naked eye, it was not possible in many cases to discover those lesions of brain structure which produce and accompany insanity. But now, by the recent application of the microscope, the minute structure of the brain is revealed, and pathologists can trace distinctly the seat and nature of those morbid changes which are the real essence of insanity. Hence Schroeder Van der Kolk, an eminent German anatomist, says that 'he does not remember to have dissected the brain of one lunatic during the last twenty-five years without finding a satisfactory explanation of the phenomena observed during life.' Dr. A. Combe, in his work 'On Mental Derangement,' lays down this principle: 'Every derangement of function is accompanied by disorder, either in the structure or mode of action of the organ which performs it, and without the removal or cure of which the function cannot be restored to its healthy state.' From ignorance of, or want of confidence in, the fact that the brain is the medium for manifesting mind, our predecessors were contented to regard mental derangement as an affection of the immaterial principle of mind, or as a particular dispensation of Providence which they could not be expected either to understand or to remedy; and, accordingly, while this view continued to influence their practice, all sorts of barbarous and useless measures were adopted against the miserable patients. The latest expression of authoritative opinion upon this subject is Dr. Maudsley's, in his Gulstonian Lectures 'On the Relations between Body and Mind.' That gentleman thus speaks:—'I have given a survey of the physiology of our mental functions, showing how indissolubly they are bound up with the bodily functions, and how barren must of necessity be the study of mind apart from body. I now propose to show that the phenomena of mental derangement bear out fully this view of its nature, that we have not to deal with disease of a metaphysical entity, which the method of inductive inquiry cannot reach, or the resources of medical art touch, but with disease of the nervous system, disclosing itself by physical and mental symptoms. It seems then that the question is concluded both by reasoning and medical testimony, and it appears to me that insanity is just as much bodily disease as paralysis and apoplexy, which are notoriously affections of the brain and therefore admitted to be bodily disease.'"

The practical issue of this judgment was an order given by the Secretary of State for granting sick allowance in cases of insanity.

I remain, Sir, your obedient servant,
W. U. Whitney.

Great College-Street, Westminster.

PAYMENT FOR DISTRICT MEDICAL RETURNS.

To the Editor of The Lancet.

Sir,—I have received a letter from the Local Government Board, dated Sept. 13th, 1875, acknowledging my report, in which the following statement occurs, which will, I think, be received with satisfaction both by district medical officers and medical officers of health, and points out the wish of the Local Government Board to interpret the new Public Health Act in a just and liberal spirit.

"Adverting to your remark, on page 28 of the Report, that there seems to be no means in the present law of giving a district medical officer remuneration for information respecting sickness in his district, which he may furnish to the medical officer of health, I am directed to state that the Board consider that it is competent for the urban sanitary authority, if they think proper to do so, to enter into an arrangement to pay the district medical officer reasonable remuneration for supplying you, as medical officer of health, with information which you require for the efficient discharge of your duties."

Feeling that the refusal of the district medical officers, both in my urban and rural sanitary districts, to furnish me with returns was purely a matter of principle, in which I myself sympathised, I thought it right to mention the matter in my report, and it gives me much pleasure to find that it has elicited so important a decision.

I am, Sir, yours faithfully,
Horace Swete, M.D.,
Medical Officer of Health, Droitwich Rural and Urban Sanitary Districts.

Leamington, Sept 14th, 1875.

PARIS.

(*From our own Correspondent.*)

MEETING OF THE FRENCH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE AT NANTES.

The accounts which have reached Paris of the fifth session of the French Association for the Advancement of Science, recently held at Nantes, all speak of the very great success of the meeting. In all the sections members were most active; several important communications were made, and gave rise to valuable debates. Of the proceedings of the medical section I shall give you a special and condensed account in my next letter. In the section of Anthropology the communications of Professors Vogt and Broca were especially interesting.

The local authorities had done their best to enhance the interest and attractions of the Nantes meeting, and all the notable inhabitants of the city of the west and its environs had co-operated in ensuring its success, either by joining as members, or exhibiting private collections of art or science, or sending invitations to their estates, &c.

Many sectional or general excursions were made into picturesque old Brittany, full of prehistoric associations and remains and of present attractions. The Agricultural section visited the School of Agriculture of Grandjouan under the guidance of M. Rieffe, who had invited them to luncheon, and the model estates of M. de la Haye-Jousselin, who, with great courtesy, accompanied them over his grounds.

The anthropologists made two interesting excursions—one to the Lac de Grandlieu, where (*inter parentheses*) they were very nearly arrested by a suspicious *gendarme*, whose mind was made uneasy by the wanderings of these strangers; the other to the renowned commune of Bourg de Batz, a small peninsula between le Pouliguen and le Croisic, inhabited by the descendants of four or five families, and remarkable for the robust vigour and developed stature of the inhabitants, especially the women. As the system of intermarriages is exclusively practised there, the handsomeness and strength of the inhabitants bring out the theory that consanguineous marriages are bad only in the case of diseased or degenerated relatives.

One general excursion was a protracted one: it lasted three days, and included Auray, Lorient, Belle-Isle, Vannes, Locmariaquer, and Gaor Inis. The visit to this last locality was especially interesting, on account of its immense dolmens and the curious hieroglyphic figures with which they are covered, and which have until now baffled the interpretation of savants.

It is decided that the next meeting of the Association shall be held at Clermont-Ferrand, amidst the beautiful mountain districts of Auvergne, and that Professor Dumas, the illustrious chemist, will be president.

CONTEMPLATED CATHOLIC UNIVERSITIES.

Great exertions are being made amongst the religious associations and clergy for the rapid foundation of several universities. As you are well aware, a recent vote of the National Assembly has authorised the establishment of free universities besides those belonging to the State. A council of bishops has been held here, and it has been decided that Paris shall have its free university, supported by the clergy, and including the faculties of law, letters, and sciences, besides courses of medicine. It is expected that the university will be opened in November, one of the clerical organs here, *l'Univers*, asserting that the requisite number of professors and students already exists. The Bishops of Toulouse have also met for the purpose of founding a like university for the South of France, and those of Anger are likewise busy preparing an establishment in the West.

MEDICAL DESCENT OF MARSHAL MACMAHON.

In the last issue of the *Journal des Connaissances Médicales*, there was an interesting piece of news touching the medical descent of the President of the French Republic, who, according to the article, is descended from, or nearly related to, several medical men. Thus his grandfather, Jean Baptiste MacMahon, was a medical man, and a Doctor of the Faculty of Reims; his grand uncle, Dr. Jean MacMahon, was a graduate of Paris; and more recently, his cousin, Patrice MacMahon, also a Doctor of Paris, was Librarian to the School of Medicine of this city.

Amongst the medical talk of last week there are some topics of interest to your readers. Thus it is said that Professor Depaul, who occupies the clinical chair of Accouchements at the Faculty, has been invited to Brazil to assist the daughter-in-law of the Emperor in her approaching confinement. His honorarium will be a handsome one, £10,000, and £2000 for travelling expenses. Duchenne de Boulogne, the well-known promoter of the medical uses of electricity, and the author of the exhaustive treatise on the same subject, is suffering severely from illness. Bouillaud, the veteran clinical professor at the Charité, is contemplating retirement from hospital work, not on account of health, notwithstanding his ripe old age of eighty, but to seek rest and quiet after a life of hard work, crowned by every honour and success. The illustrious physician is full of life and vigour, and his intellectual abilities and powers of oratory are as bright as ever.

Paris, Sept. 15th, 1875.

Bequests, &c., to Medical Charities.—Mrs. Mary Price, of Woodhatch, Reigate, bequeathed £500 to the Sussex County Hospital, £300 to the Reigate Cottage Hospital, £300 to the Surrey Dispensary, £200 to the Ophthalmic Institution in London, £200 to the Truss Society, £100 to the Medical Benevolent Society, Epsom, and £100 to the Asylum for Idiots, Earlswood. Mr. Charles James Kilpin, of Ossington-street, Bayswater, bequeathed £100 to University College Hospital and £100 to the Hampshire Hospital.

Medical News.

Apothecaries' Hall. — The following gentlemen passed their examination in the Science and Practice of Medicine and received certificates to practise on Sept. 2nd and 9th:

Angove, William Thomas, Mount Pleasant, Cambourne.
Dowding, Alex. William Woodman, Leighton Buzzard.
Duke, Herbert, Clapham-road.
Grimwood, Harry Charles, Stowmarket, Suffolk.
Lendon, Edwin Harding, Maidstone, Kent.
Mapei, Luigi Vincenzo, Golborn, Lancashire.
Wickham, Henry, Tetbury, Gloucestershire.
Whitmore, William Tickle, West London Hospital.

The following gentlemen passed the Primary Professional Examination on the same days:—

Alexander Boswell, Geo. Adolphus Boodle, and Thomas Baker, St. Bartholomew's Hospital; Edward Nundy and John Webster, University College; Reginald Paul, Middlesex Hospital; James Taylor Tweedale, Owens College, Manchester.

It is stated that Mr. Baily Denton forwarded to the corporation of Colchester a scheme for intercepting and treating the sewage of the town, which now falls into the Colne. The cost of the sewage works is estimated at £30,000, and the annual cost of treating the sewage at £2000.

Glasgow Medico-Chirurgical Society. — The following office-bearers for the ensuing session were elected at a meeting on the 3rd inst.:—President: Dr. James Morton. Vice-Presidents: Dr. D. Richmond (Paisley), Dr. Robert Perry. Council: Dr. R. Stewart, (Coatbridge), Dr. James Scanlan, Dr. Alex. Patterson, Dr. James Dunlop, Dr. D. Taylor, (Paisley), Mr. A. Macfarlan, Dr. Thomas Reid, Dr. T. M'C. Anderson. Secretaries: Dr. Joseph Coats, Dr. Gavin P. Tennant. Treasurer: Dr. Hugh Thomson.

Sir Charles Locock's Will. — The will and codicil, dated July 22, 1871, and December 7, 1872, of Sir Charles Locock, Bart., was proved on the 18th ult., the personal estate being sworn under £100,000. He gives the various presents received from Her Majesty the Queen, the Emperor and Empress of the French, the Prince Imperial, the Crown Prince of Prussia, the Duc de Nemours, to his eldest son; he also leaves upon trust for him absolutely, as his successor in the baronetcy, £50,000; upon trust for his son Frederick for life, £5000; and the residue equally between his sons, Charles Brodie, Alfred Henry, Sydney, and Herbert.

The Hospital Sunday Fund.—Some little surprise has been expressed at the delay in distributing the fund collected for the metropolitan hospitals and dispensaries on Hospital Sunday, the 13th June last. The fund, up to Monday, and including interest, amounted in the aggregate to £26,703 7*s.*, as against a total of £29,817 3*s.* 9*d.* received last year. It will be divided within the next fortnight among 122 institutions — namely, seventeen general hospitals, four chest hospitals, eight children's hospitals, four lying-in hospitals, five hospitals for women, and twenty-one other special hospitals, including dental and homœopathic hospitals, seven convalescent hospitals, one fever hospital, three cottage hospitals, forty-eight dispensaries, and four infirmaries and sanitaria. The arithmetical bases of distribution have been provisionally settled by the committee, but these may probably be affected by the verbal statements which the managers of the special hospitals may make in explanation of their accounts and position. Deputations from twenty of such institutions have, or had, to be seen, and the delay has arisen through the difficulty in getting people together in the holiday season.—*The Times.*

Medical Appointments.

Allison, J., L.F.P. & S. Glas., has been appointed Medical Officer of Health for the Bridlington Urban Sanitary District, vice Denton, resigned.

Archer, A. L., M.D., L.R.C.S.Ed., has been appointed Visiting Surgeon for Plymouth, Devonport, Dartmouth, Ivy Bridge, and Plympton, under the provisions of the Contagious Diseases Acts (Women), vice Digan, deceased.

Bannister, W., M.R.C.S.E., has been appointed Medical Officer and Public Vaccinator for the Bedhampton, Farlington, Hayling North, and Hayling South Districts of the Havant Union, vice Stedman, superannuated.

Beavan, J., F.R.C.S.E., has been appointed a Surgeon to the Brighton Hospital for Sick Children, vice Johnstone.

Berry, O. W., M.R.C.S.E., has been appointed Medical Officer for the Lower Wimbledon District of the Kingston-on-Thames Union, vice Johnson, resigned.

Callan, P., L.K.Q.C.P.I., L.M., L.R.C.S.I., has been appointed Medical Officer to the Workhouse and Fever Hospital, Ardee Union, Co. Louth, vice M'Iver, deceased.

Day, Mr. G. C., has been appointed Resident Medical Officer, for a temporary period, to the Notting-hill Provident Dispensary and Maternity, vice Morrill, resigned.

Edwards, B., L.R.C.P.L., M.R.C.S.E., has been appointed a Surgeon to the East Suffolk and Ipswich Hospital, vice Sampson, resigned, and appointed a Consulting Surgeon.

Fennell, D., L.R.C.S.I., has been appointed Resident Medical Officer to the Dudley Dispensary, vice Bateman, resigned.

Glen, J., M.D., C.M., has been appointed Medical Officer for No. 3 Division of No. 3 District of the newly formed Middlesborough Union.

Graham, J., M.R.C.S.E., has been appointed an Hon. District Surgeon to the Royal South London Dispensary, St. George's-cross, vice Verdon, resigned.

Harris, W., F.R.C.S.E., has been appointed House-Surgeon and Secretary to the Royal Cornwall Infirmary, Truro, vice James, appointed House-Surgeon to the Hull and Sculcoates Dispensary.

Hart, E. J., M.R.C.S.E., has been appointed Medical Officer for the Brighton District of the London, Brighton, and South Coast Railway Provident Society, vice Philpott, resigned.

Hearn, R. T., M.B., L.R.C.S.I., L.M., has been appointed Resident Medical Officer and Hon. Secretary to the Bournemouth General Dispensary, vice Hirons, resigned.

Hedley, J., M.R.C.S.E., has been appointed Medical Officer for the D District of the Middlesborough Union.

Hobley, S. H., L.R.C.P.L., L.R.C.P.Ed., M.R.C.S.E., has been appointed Medical Officer to the Loyal Englishman Lodge of Odd Fellows, Manchester Unity, Southampton.

Hollis, E., M.B., C.M., has been appointed House-Surgeon to the Royal Portsmouth, Portsea, and Gosport Hospital, vice Madeley, resigned.

Howson, J. J., L.S.A.L., has been appointed House-Surgeon to the Stockton Surgical Hospital.

Johnstone, A. A. W., F.R.C.S.E., has been appointed a Consulting Surgeon to the Brighton Hospital for Sick Children.

Jones, R., F.R.C.S.E., has been appointed Consulting Surgeon to the Warneford, Leamington, and South Warwickshire Hospital, on resigning as Surgeon.

Kebbell, W., M.R.C.S.E., L.R.C.P.L., has been appointed Junior Assistant Medical Officer to the Three Counties Asylum, Beds.

Keith, A., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer for No. 2 Division of No. 3 District of the Middlesborough Union.

Laidler, J., M.R.C.S.E., has been appointed Medical Officer for the No. 2 District of the Middlesborough Union.

Lloyd, S., M.R.C.S.E., has been appointed Medical Officer for the Workhouse of the Parishes of St. Giles-in-the-Fields, and St. George, Bloomsbury, vice Bennett, resigned.

Longbotham, G., M.R.C.S.E., has been appointed Medical Officer for the A District of the Middlesborough Union.

Lucas, H., M.R.C.S.E., has been appointed Medical Officer of Health for the Godmanchester Urban Sanitary District, vice Syson, whose appointment has expired.

Mackenzie, R. F., M.B., L.R.C.S.Ed., has been appointed Medical Officer for the C District of the Middlesborough Union

M'Millan, H., M.D., C.M., has been appointed Resident Medical Officer to the Macclesfield Infirmary, vice Boulger, resigned.

Morris, J., M.R.C.S.E., has been appointed a Surgeon to the Warneford, Leamington, and South Warwickshire Hospital, vice R. Jones, resigned.

Nally, W. J., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Attendant to the Royal Irish Constabulary, Kinvarra, Co. Galway, vice Hynes, deceased.

Owens, Dr. —, has been appointed Medical Officer, Public Vaccinator, and Registrar of Births &c., for the Ballycroy Division of the Achill Dispensary District of the Newport Union, Co. Mayo, vice Roe.

Parker, W. A., L.D.S. R.C.S.E., has been appointed one of the Consulting Surgeon-Dentists to the Birmingham Dental Hospital.

Pearson, T. R., M.D., L.R.C.P.Ed., M.R.C.S.E., has been appointed Medical Officer for the B District of the Middlesborough Union.

Pierce, E., M.D., F.R.C.S.Ed., L.F.P. & S. Glas., has been appointed Public Vaccinator for the Llanrhaiadr District of the Ruthin Union, vice Williams, resigned.

Powell, J., M.R.C.S.E., has been appointed Medical Officer for the Penbryn District of the Newcastle-Emlyn Union, and Medical Officer of Health for the Penbryn Sub-district of the Newcastle-Emlyn Rural Sanitary District, vice Evans, deceased.

Rogers, E. C., M.R.C.S.E., has been appointed Senior Assistant Medical Officer to the Three Counties Asylum, Beds, vice Dr. Sutherland Rees-Philipps, resigned.

Rosten, W. M., M.D., M.R.C.S.E., has been appointed Medical Officer and Public Vaccinator for the Yardley District of the Solihull Union, vice Warner, resigned.

Sawyer, R. H., M.R.C.S.E., has been appointed Medical Officer of Health for the Shaftesbury Rural Sanitary District.

Seed, W. H., M.B., C.M., has been appointed Second Assistant Medical Officer to the Warwick County Lunatic Asylum, Hatton, vice Peacock, resigned from ill health.

Smailes, T., M.R.C.S.E., has been appointed Medical Officer to the Borough Police, Honley, Yorkshire, vice Todd, deceased.

Sleightholme, J. P., L.R.C.P.L., M.R.C.S.E., has been appointed Medical Officer for No. 1 Division of No. 3 District of the Middlesborough Union.

Staines, J. F., L.R.C.P.Ed., L.F.P. & S. Glas., has been appointed District Medical Officer to the Parishes of St. Giles-in-the-Fields, and St. George, Bloomsbury, vice Bennett, resigned.

Thompson, J., L.R.C.P.Ed., M.R.C.S.E., has been appointed Medical Officer for the Higher District of the Aysgarth Union, Yorkshire.

Wade, A. L., M.D., L.R.C.S.I., has been appointed Assistant Medical Officer to the Warwick County Lunatic Asylum, Hatton, vice Woods, appointed Medical Superintendent of the Kerry Lunatic Asylum, Killarney.

Waterworth, E. A., M.D., M.R.C.S.E., has been appointed Medical Officer and Public Vaccinator for the Carisbrooke District of the Isle of Wight Union, vice Wilkins, resigned.

Births, Marriages, and Deaths.

BIRTHS.

Atkinson.—On the 2nd inst., at Bampton, the wife of J. P. Atkinson, M.D., of a son.

Corley.—On the 2nd inst., at Lower Baggot-street, Dublin, the wife of A. H. Corley, M.D., of a daughter.

Watts.—On the 23rd ult., at Sharnbrook, Beds, the wife of A. N. Watts, L.R.C.P.Ed., of a son.

Weir.—On the 29th ult., at St. Mungho's, Great Malvern, the wife of A. Weir, M.D., of a son.

MARRIAGES.

Bligh—Searle.—On the 7th inst., at All Saints, Upper Norwood, Samuel Edmund Bligh, M.B., C.M., British Guiana Medical Service, to Eliza Constance, only daughter of Samuel Searle, Esq., of Upper Norwood.—No Cards.

Douglas—Robertson.—On the 8th of April, at Dunedin, Otago, N.Z., T. Kennedy Douglas, M.B., C.M., to Johanna, youngest daughter of the late D. Robertson, Esq., of Friarton, Perth, N.B.

Harricks—Vokes-Dudgeon.—On the 22nd of May, at Trinity Church, Port Mackay, Queensland, J. Hugh Harricks, M.R.C.S.E. (son of John Harricks, Esq., Surgeon, of Liverpool), to Christmas Annette, eldest daughter of T. Vokes-Dudgeon, Esq. (late of H.M.'s 99th Regiment), Collector of Customs, Port Mackay.

Munro—Taylor.—On the 8th inst., at London-road, Kilmarnock, Robert Munro, M.A., M.D., of Kilmarnock, to Anna Black, youngest daughter of Wm. Taylor, Esq.

DEATHS.

Adams.—On the 5th inst., at the residence of his nephew (Dr. A. M. Adams), Lanark, W. D. Adams, M.D., F.R.C.S.E., of Hyères, France, and formerly of Edinburgh. Friends omitted will please accept of this intimation.

Agnew.—On the 3rd inst., at Islington, Liverpool, Wm. Agnew, M.D., aged 72.

Bennett.—On the 1st inst., at North Shields, Robt. Bennett, Surgeon, aged 29.

Bennie.—On the 13th inst., at Chatham-place, Brighton, Andrew Bennie, L.R.C.P.Ed.

Crane.—On the 6th inst., at Leicester, E. J. Crane, L.R.C.S.Ed., Surgeon-Major Royal Artillery, aged 41.

Gillespie.—On the 7th inst., at Accrington, Lancashire (of congestion of the brain), John Morris Gillespie, M.D., L.R.C.S.Ed., aged 49. Deeply regretted.

Harrington.—On the 30th ult., at Fisher-street, Swansea, N. Harrington, M.R.C.S.E., aged 44.

Headland.—On the 4th inst., at St. Leonard's-on-Sea, F. W. Headland, M.D., aged 45.

Hooper.—On the 9th ult., at Battersea, Thos. Robt. L. Hooper, M.R.C.S.E., aged 38.

Thring.—On the 2nd inst., at Batheaston, R. S. O. Thring, M.D., aged 57.

[N.B.—*A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*]

Notes, Short Comments, and Answers to Correspondents.

Magnifying an Office.

Those useful officials, the inspectors of nuisances, are, it seems, aggrieved at the prominence given to medical officers of health under the new Act. They are moved to indignation by having been described as "underlings and henchmen" of the medical officers. We should be sorry to offend the sensibilities of men who, if only intelligent and industrious, will do excellent service; but it may not be tolerated that a class of subordinate and irresponsible officers, who cannot possibly possess the knowledge requisite to enable them to act except under direction, should be allowed to usurp the functions of those above them. Great tact will evidently be required in the management of these officials. They complain that medical officers are sometimes "too overbearing." This is an evil against which there should be a special watch kept by those who desire to live and work pleasantly. The most serious peril we recognise is that which must result from the inspectors playing into the hands of inert or cantankerous "local authorities." Medical officers will do wisely to clear their way of this danger by an early and courteous assertion of the position they occupy. The inspector of nuisances is not the colleague or in any sense the coadjutor of the medical officer of health. He is an independent officer of the local authority, and in so far as he comes into business relations with the officer of health, he is his subordinate. Practically, the inspector of nuisances is a person whose duty it is to look after and report minor matters affecting the health of a district. The more important concerns of the district are all under the sole superintendence of the medical officer, and for their due administration he is personally responsible. There can be no sharing authority with the inspector, and we venture to hope so unprofessional a course of conduct will not anywhere be adopted or allowed.

Mr. Geo. Fenton.—Any guardian may sit upon a general or special committee to which he has been regularly elected by his colleagues, but not otherwise, and none other than those so elected can attend or vote.

Dr. R. Caton, (Liverpool.)—We shall be very happy to receive it.

Illegitimate Mortality in Glasgow.

The vital statistics of Glasgow, as handled by its medical officer of health, Dr. Jas. B. Russell, are full of interest which is more than local, and contain valuable information illustrative of the waste of life in large towns—information that may be looked for in vain in nine out of every ten medical officers' reports. Dr. Russell's report for the year 1874 includes some very suggestive figures bearing upon the infantile mortality of illegitimate children. During the year 1785, illegitimate children were born in the city equal to 8·5 per cent. of the total births; this number and proportion differed but slightly from those in recent years. Infant mortality in Glasgow during 1874, measured by the proportion of deaths under one year to births, was equal to 16·0 per cent., against 15·5 in London, 20·0 in Leeds, 21·5 in Leicester, and 23·3 in Liverpool. Among the infants born in wedlock the mortality, measured in this manner, was equal to 14·9 per cent., whereas among the illegitimate infants it was equal to 27·7 per cent. If the mortality among the illegitimate infants had been at the same rate as prevailed among those born in wedlock, the deaths of illegitimates, under one year, would have been but 266 instead of 495; in other words, 229 infants under one year of age died in Glasgow, victims to the accident of their being born of unmarried women. In four of the registration subdistricts of Glasgow the proportion of deaths of illegitimate infants under one year, to illegitimate births, exceeded 30 per cent., and in one was equal to 32·7 per cent. It is to be regretted that information on this point is not more frequently given in English health reports, more especially as statistics of this character, beyond serving as a wholesome check upon much indirect infanticide, afford the means for discovering the localities in which baby-farming may be carried on.

Mr. Thomas Walley, (Edinburgh.)—Declined with thanks.

Vivisection *v.* Sport.

To the Editor of The Lancet.

Sir,—Now that the vivisection question is in a fair way of being settled, it would be well if Lord Hartismere or some other of the philozoists would extend their sympathies to another class of suffering creatures—viz., those which are subject to *torture* as objects of *sport*, or in the course of preparation as articles of food. It is well known that every year thousands upon thousands of game birds, hares, and rabbits, are more or less mutilated without being killed outright; that they escape into cover, riddled with shot or with shattered limbs, to die a lingering death of torture, or in some few instances to recover, after a long period of suffering, with crippled legs or wings. Who has not seen, after a *battue*, hares and rabbits limping away on three legs, and found them afterwards with the broken bones protruding? Who has not at the table met with instances of bones of game animals wonderfully united by overlapping of the broken ends? Did they ever think of the amount of misery these poor creatures endured? So with pigeons at a match. How many escape to die in solitude? But we are told that this is sport, and sport is necessary. Therefore the torture of these animals is allowable! Well, take the case of sheep which the farmer puts on his turnips to eat off the tops, and, in order that they may not eat the roots, breaks off all the front teeth. Is there any cruelty in this practice? Or the frequent bleeding of calves to produce white veal. Would it come within the sphere of the Vivisection Committee, after considering with Mr. Leo Hunter the claims of the "expiring frog," to turn their steps to the nearest fish-market, and watch the operations of an old fishwoman chatting to her neighbour and skinning eels? See her deliberately cut off the brute's head; then turn to make a remark to her friend; then drag the skin half way down the body; another bit of gossip, and so by degrees the skin comes off. Is the eel dead the while? By no means—writhing and twisting about, and full of life (of a sort) for hours after. But then this is not an experiment. At any rate, if it is, a physiologist must not make it.

It would be easy to multiply examples of torture far exceeding in amount and degree anything that is done by physiologists; and while admitting that experiments should be conducted with as little cruelty as possible, and always under the influence of anæsthetics, it is not easy to understand why the same measure of mercy should not be dealt out to a far more numerous class of sufferers. In the terms of Lord Hartismere's Bill, why should not "the performance of vivisection (for sport) require a special licence at the cost of £10?" "with power to a justice of the peace to issue a search warrant," and with a "definition of the term 'vivisection.'" Why should not the Bill be entitled "A Bill to Prevent Abuse and Cruelty in the Destruction of Animals for the purpose of *Sport* or Food"? By it any person for these objects may torture a live animal, "provided that the animal be first *made insensible* and killed afterwards." "Licensed persons may torture without the use of anæsthetics, provided certain conditions are complied with—viz., that the operation is solely for the purpose of *sport* &c., and that insensibility would frustrate the object," &c. &c. "A register of all such tortures is to be kept," &c.

I would commend this subject heartily to the consideration of the Vivisection Committee on the termination of their present labours.

I am, Sir, yours truly,
A Game Bird.

September, 1875.

Holidays.

Mr. T. F. Sagar approves of our views on holidays for medical men, and thinks they should be good ones—not for a night or two. He points out the difficulties, of which the difficulty of getting a good *locum tenens* is one of the greatest. This is true; but the difficulties are not insuperable.

Mr. John Milne.—We should have been glad of the newspaper reports of the case. For purposes of comment these are preferable to private reports. It will be seen that the case is noticed in another page.

A. B.—We see no harm in the notice to which our correspondent objects. It can serve no private end.

Mr. Bollon, (Doneraile.)—Apply to Messrs. Baillière, medical publishers, King William-street, Strand.

J. A.—We never recommend a particular physician or surgeon.

Death of a Child from Uræmic Poisoning.

On Tuesday, the 31st ult., Mr. Donaldson, the deputy coroner for East Middlesex, held an inquiry at the "Lord Cecil" Tavern, Lower Clapton, into the circumstances attending the death of a child named Henry Vincent Gurney, aged four years. Mr. Thomas Gregory Gurney, the father of the deceased, residing at 52, Rushmore-road, and a clerk in the Law Institution, stated that the child about four months ago suffered from congestion of the kidneys. Last June twelvemonth he had scarlet fever, and before he was two years of age had hydrocele, which was followed by his becoming ruptured. Witness named the medical men who attended the deceased, and added that on the 27th ult. he appeared worse, and he (witness) administered some simple remedies, but had no reason to suppose when he left home that the child would die in the meantime. Upon his return that evening, however, he learned that death had taken place about half-past six o'clock. Dr. Joseph, assistant to Dr. Aveling, said that a few months ago the deceased was treated for Bright's disease, and seemed to get a great deal better. There had been no post-mortem examination, as witness was satisfied death was due to uræmic poisoning from disease of the kidneys. The jury returned a verdict in accordance with the medical testimony.

Mr. C. E. Garman.—As our correspondent says a communication has been made to the "proper channel," we cannot further interfere in the matter.

"Two Unusual Cases."

To the Editor of The Lancet.

Sir,—A correspondent, writing from Berwick, and signing himself "M.D.," sent me, through the medium of the halfpenny post, a card to the effect that in my report of "two unusual cases" in The Lancet of the 14th ult., Case 1 was epileptiform, and the fractured acromion the result of the kick of a horse frightened by the coachman falling down. He states, in addition, that the "bitten and bleeding tongue *clearly points* to an epileptic seizure"; that, "unless the patient be put under the influence of bromide of potassium, he will most probably have another similar seizure ere long, irrespective of any injury"; and concludes with, "If so, pray say so in The Lancet."

Now, Sir, more than six weeks have elapsed since the accident (no great length of time certainly), and I was last Sunday informed by Dr. Elliott, in whose practice the case occurred, that no sign of epilepsy had yet presented itself. Added to this, I, when called in on the morning of the accident, before examining the body of the patient for injury, very closely questioned the man and his friends as to the occurrence or non-occurrence of fits of any description—the possibility, nay, further, the probability, of epilepsy being *then* uppermost in my mind; but neither in the past history of the man nor up to this date has epilepsy or any form of seizure existed. I am constrained, therefore, to adhere to my former opinion; and so far from the bitten and bleeding tongue *clearly pointing* to an epileptic seizure, it, to my mind, most distinctly indicates that such complications may, and, as we *nearly* all know, do, in many instances, result from the application of sudden violence, altogether apart from and foreign to epilepsy.

I have replied to "M.D." somewhat sooner than he desired me; but the performance of two duties suggest themselves—1stly, to explain that "M.D.'s" view had only been by myself relinquished when I no longer had reason to retain it; and 2ndly, to bring before the notice of "M.D." what appears to me a great error on his part. I think that "M.D." would not have, on maturer reflection, addressed any description of *anonymous* communication to any individual, especially one *uncovered*, and *upon a professional subject*. I am willing to presume that it was done unthinkingly; but if not, the habit of doing so savours either of ignorance and a want of knowledge of the world, or of discourtesy, and occasionally gives rise to considerable inconvenience and annoyance. Most decidedly, I think, correspondence upon such subjects should be forwarded under cover. Moreover, what a person or individual objects to put his name to, should not be written, still less sent.

I am, Sir, your obedient servant,
Edward C. Anderson, B.A. Caius Coll. Cambs.
Catford Bridge, Sept. 6th, 1875.

A Young Surgeon.—It is not easy to reply to our correspondent's query. We do not think a medical witness is strictly entitled to more than a guinea per diem, no matter how many cases he may have to attend at a particular sessions; but in practice he will probably receive a little more than this, as he would have something with each subpœna, and the sum for daily attendance would probably be apportioned between the several cases.

The Yeovil Case.

As this is *sub judice*, our correspondent must excuse us from going into the matter.

A Growing Evil.

To the Editor of The Lancet.

Sir,—The enclosed card was placed in my hands by the husband of one of my patients, recently confined. It is evident these cards are posted off to all names appearing in the list of births in the daily papers, and must in some cases work very detrimental to the cause of vaccination. This is worse than quackery, and a proper case for the Medical Council to take up and prosecute, not only in support of our profession, but to prevent the public being misled by such deceitful means. If such slurs and the persistent infringements by quacks upon our profession are allowed to continue without a decided check, what use is there in our registering and paying our five-guinea fee? These fees are supposed to form a fund which should be used by the Medical Council to suppress quackery of all sorts and support the professional status. If not, the sooner the Medical Council is put in possession of such powers the better.—Yours faithfully,

Rickmansworth, Sept. 7th, 1875. Roderick W. Henderson.

*** The enclosure is an offensive post-card, signed by "W. Young, Hon. Sec. to the Society for Suppressing Compulsory Vaccination." It is quite beneath notice.—Ed. L.

The Culinary Art.

The School Board of London has arranged to have 300 girls selected from its schools taught cookery by the teachers of the National Training School in two centres—one in Marylebone, the other in Greenwich. Five free Scholarships in this much neglected but important branch of knowledge are offered by the Society of Arts, and the Education Department gives 4*s.* a year to public schools on behalf of each girl taught cookery according to the recognised code. Thus we shall by and by, it may be hoped, lessen the great disparity which subsists between ourselves and our French neighbours in the matter of the skilful and economical preparation of food.

Army Medical Department.

To the Editor of The Lancet.

Sir,—If any unprejudiced person were to judge of the condition of the Army Medical Department from the letters and articles that have lately been written about it in The Lancet and other periodicals, or even from some of the speeches in Parliament during the last session, he could hardly avoid coming to the conclusion that the medical officers were dissatisfied, and had good reasons for being so. Nevertheless, the "authorities" not not only seem to be indifferent to any existing causes of discontent, but have just gone out of their way to devise an altogether new source of irritation. I refer to clause 125 of the War Office Circulars for the present month, a copy of which I shall presently subjoin, lest the new rules concerning the sick leave of medical officers should not have attracted your attention. Hitherto medical officers, when placed on the sick-list, have enjoyed the same privileges as regimental officers, and have neither been mulcted in pay nor subjected to curtailment of their ordinary leave on account of any time that they may have spent on the sick list. But the object of this new regulation appears to be to deprive them of this advantage. If a medical officer hereafter should suffer from illness—say typhoid or any other fever,—and should be compelled thereby to remain for more than a month on the sick-list, even though such illness may have been contracted in the performance of his duties, he would by this regulation be liable to lose not only his pay and allowances for all sick time exceeding one month, but also a portion of his privilege leave, unless the general or other officer commanding recommended that this part of the order should not be enforced. Nay more. To those who are acquainted with the form upon which the pay and allowances are drawn, it will not appear at all improbable that these penalties will fall upon any medical officer who may happen to be sick for more than thirty days altogether in any one year; for the vagueness of the order is evidently open to this construction. We can well imagine the air of surprise and innocence with which medical officers, when they complain of this new order, will be told that they are only placed in the same category with other departmental officers, and that therefore they have no special or legitimate grievance. Such arguments have been used before, and are well suited to throw dust in the eyes of those who are not already sceptical as to the value of official statements. But it cannot be denied that, although it may please the authorities to style the medical service of the army a "department," this restriction of sick time is an *innovation* as regards the medical officers, whatever it may be with respect to the officers of other departments. After all, what are the other departments? They are the chaplain's department, the control department, the clerks of works, and a few others. But the medical officers are not on the same footing with chaplains, control officers, and clerks of works, either in respect of their duties or of their liability to tropical service. A chaplain, for example, will seldom require to go on the sick-list, for he must be very ill indeed to be incapacitated for the performance of such duties as ordinarily fall to his lot during the week; and even if he should require to declare himself unequal to his Sunday's duty, it would be seldom that he would remain on the sick-list when the Sunday had passed. Nor are the duties of the control officers usually such as require a large expenditure of mental or bodily energy. Probably the majority of the control officers do their work in comfortable offices, where they are not exposed to the weather, and where they have no difficulty in postponing until the morrow any task to which they may feel themselves unequal to-day. Neither control officers nor chaplains have any night work, except on the rarest occasions, and whenever they are ailing they may very certainly calculate on a whole night's rest in bed. With the medical officer all this is very different. Ill or well, if not on the sick-list, he is liable at any moment to be called upon to face the gravest emergencies. He has no power of choice; he cannot postpone his serious case for to-morrow's consideration; nor can he excuse himself from turning out of his warm bed in the middle of the most inclement night when called upon by those who are entitled to his services. Again, neither control officers nor the chaplains are required to serve in India; and it is Indian service, as is well known, that breaks down the health of the medical officer and shortens his life. Lastly, neither chaplains nor control officers are exposed to the contagion of disease as medical officers are. For all these reasons it is manifestly most unjust that a restrictive rule, which has hitherto been applied only to *quasi*-civilians, should now be brought to bear upon those so much exposed to the causes of disease as medical officers.

However, it is perhaps fortunate that this season of the year has been chosen for the announcement of this innovation. The medical schools are about to reopen, and medical students will now be deciding as to their future career. Let us hope that the professors and teachers in their introductory addresses will warn all medical students against entering the medical department of the army—a department in which service is now neither pleasurable nor profitable, and for which there is clearly no prospect of better things.

I am, Sir, your obedient servant,
September, 1875. Climax.

Copy of Clause 125 *of Army Circulars, September*, 1875.

"Sick Leave of Departmental Officers.—1. When a departmental officer is sick at his station, whether in hospital or quarters, his absence from duty on account of sickness will be recorded in the form upon which his pay and allowances are drawn, *but no loss of pay or allowances will be entailed by such absence*, if duly certified by a medical officer, and *if not exceeding one month in duration*. This absence on account of sickness need not be included in the period of leave with pay allowed by Articles 442 and 448 of the Royal Warrant of 27th December, 1870, if the general or other officer commanding at the station considers that the circumstances of the case warrant such a concession."

N.B.—The original is not in italics. See Army List for September—Appendix.

Medical and Relieving Officers.

It is a monstrous anomaly of the law that in the administration of medical relief the medical officer is at the mercy or the discretion of the relieving officer, who has power to withhold articles ordered by the doctor. This relation has been the very proper subject of discussion by the Guildford Board of Guardians. They resolved to remind the relieving officer of a resolution passed by the Board in 1873, to the effect that when a recommendation given by the medical officer is refused by the relieving officer, the matter should be reported by the relieving officer to the Board. Relieving officers, as one guardian said, should be very particular in granting medical orders, and when they give them they should have very good reasons for refusing to honour the recommendations of the medical officer.

Sigma.—Our correspondent can recover for medicine and attendance. We cannot at present refer him to a case in point.

T. T.—Consult the advertising columns of this journal.

Dr. Charles White is thanked.

Mr. J. Cruickshank.—It would be against our rule to comply with our correspondent's request.

W. L. H. will find a good account of jungle fever in Reynolds's "System of Medicine," vol. i., art. "Remittent Fever."

Filth and Filters.

To the Editor of The Lancet.

Sir,—The article in your issue of Sept. 4th on "Concentrated Filth" aims such a direct blow at the system of water-filtration that we hope you will allow us a small space for a few explanatory remarks.

There can be no doubt that the present condition of the water-supply of London is all that you describe, and that the whole system of drawing water from a polluted source is a disgrace to our civilisation. Although the Water Companies nominally comply with the Act of 1852, and filter the water before delivery to the consumer, the mode of filtration adopted is so unsatisfactory that, as you justly observe, "it seems intentionally designed to ensure a subtly impure condition" of the fluid. We have in our possession samples of water drawn *directly from the mains* of five London Companies on the 3rd of May last. These samples were placed in well-stopped bottles, and when first drawn were all tolerably clear; but after standing for a few days they began to develop a large number of animal and vegetable organisms, and at this moment present the appearance of the foulest, stagnant ditch-water. It is therefore evident that the water must have contained a quantity of germs which the filtering process failed to remove, and such water stored in a cistern which the householder is too apathetic to have cleaned out, must soon get into a condition more easily imagined than described.

Of course there are plenty of people ready to suggest a remedy for the evil; and judging from the schemes which make their appearance from time to time, it would seem the easiest thing in the world to bring pure water enough from Wales or Cumberland, at a trifling cost of fifteen or twenty millions of pounds, to supply the daily necessities of four millions of human beings. But it is probable that we of the present generation shall all be in our graves before this desirable improvement can be brought into operation, and therefore paterfamilias of the period must make up his mind to put up with his present supply, and do the best he can with it under the circumstances.

Now, assuming that the house-cistern is kept scrupulously clean, we still find that the water when delivered contains sufficient impurity to render it unfit for human consumption, and the question arises, "What is the most practicable way of dealing with it so as to prevent all risk of disease resulting from its use in the household?

We all know that perfectly pure water is only to be obtained by distillation. But can distillation be made available for general purposes, and, if so, who would care to drink water so distilled? We are, therefore, thrown upon domestic filtration as the only available method of purifying our drinking-water, and that this method may be made *perfectly efficient* in depriving water of every injurious property is as capable of demonstration as that two and two make four.

Standing by the side of the bottles of water above mentioned is one containing the same water after being passed through a silicated carbon filter; and although three months have elapsed since this was done, the sample is still brilliantly clear, and will bear the most severe chemical examination, without showing the least indication of organic matter. Properly constructed, and capable of being cleaned at short intervals (every day if thought necessary), the domestic filter is the *only* apparatus at present known by which water can be effectively purified *immediately* before use; and wherever this is done, and the head of the household will take the trouble occasionally to see that his filter is kept clean, he can afford to wait patiently for a solution of the difficulty as to a better supply for the metropolis.

We are, Sir, yours faithfully,

London, Sept. 6th, 1875. The Silicated Carbon Filter Co.

Flowers *versus* Fever.

The healthful influence, both physical and moral, of the presence of flowering plants, is strongly insisted on in the last report of Dr. Ross, medical officer of health of St. Giles's district. This influence is referred to the power possessed by odoriferous plants—as the mints, lavender, mignonette, wallflower, &c.—of developing ozone, and in this way of assisting in the destruction of miasmatic poisons. The obvious inference is that, especially in crowded localities, the cultivation of sweet-scented plants should be encouraged to the greatest possible extent, in windows, forecourts, and little back yards. In the same report Dr. Ross testifies to the improved sanitary condition of the district in which he labours.

Surgeon.—We would advise our correspondent to communicate with the compiler of the Directory.

Campbell.—Society for the Relief of Widows and Orphans of Medical Men, Berners-street, London.

Dr. Kitchener has no cause to complain. The Company is not liable, as they put him upon his guard.

A Trustee.—Without seeing the site, and comparing it with other available sites, it would be extremely difficult to pronounce a definite opinion. The source of the water-supply is not mentioned. Speaking generally, it is obviously preferable to avoid the immediate vicinity of a cemetery; but the site in other respects appears to be a good one.

A. W.—It is a reliable text-book.

Mr. Geo. Fleming (Chatham) is thanked for his courtesy.

Cholera.

To the Editor of The Lancet.

Sir,—A case of cholera such as I have never before met with has occurred in my practice, the symptoms of which were so very like those of Asiatic cholera that I think it worthy of a place in your journal.

On Thursday, Aug. 26th, about 9 p.m., I was sent for to attend H. F——, residing in a colliery village about two miles from my residence, who I was informed had been ill with purging and vomiting since the night before. I found him to be a thin, wiry-looking man, aged fifty-five years. The symptoms then were purging, the stools being of a rice-water character, and vomiting of a greenish, bitter fluid. The pulse was small and weak; the surface was cooler than natural, and covered with clammy perspiration; the tongue was thickly coated with a white fur, and the tip and edges were of a dull red colour. I was informed that during the day he had been severely cramped in the legs, and that large lumps had formed on the calves. I ordered a large mustard plaster to be applied to the bowels; a mixture composed of a weak solution of soda and prussic acid, with chloric ether; and pills containing a grain of opium in each, one to be taken every two hours. The diet I ordered to consist of milk, with brandy and lime-water. On Friday morning the vomiting had entirely ceased, and all the symptoms much improved. On the Saturday he felt so well as to have (contrary to my instructions) resumed his usual diet. On Monday night I was again sent for, and was told he was then worse than before. I went, and found this to be indeed the case. The vomiting, purging, and cramps had again set in; the pulse was scarcely perceptible; the surface was quite cold, and covered with perspiration; the features were sunken, and of a dusky hue; his voice was altered much, being low and husky; his tongue was cold to the touch, and thickly coated; his urine was suppressed, he having passed none all day; his intellect was quite clear, and he answered all questions readily. A mustard plaster was again placed over the bowels, and the previous treatment resumed. Hot bottles were also placed round his body. Thinking the bladder might contain urine, I used the catheter, but to no effect. I was particularly struck with the difficulty in passing the instrument, owing to a spasmodically contracted state of the urethra. On Tuesday morning I again saw him. To all appearance he was then dying. There was no pulse at the wrist; the surface was intensely cold, as was also the tongue; the vomiting had ceased, but the purging continued; the stools were still of a rice-water character, having a most offensive odour. During the night he had passed no urine. I ordered a mustard plaster to be laid over the kidneys, and brandy and milk to be continued. At 11 p.m. he had a fit, which was followed by others until 6 a.m. this morning, when he died.

I am, Sir, yours &c.,
W. Bennett, L.R.C.P. Edin., &c.

Chester-le-Street, Durham, Sept. 1st, 1875.

A Constant Reader of The Lancet, (New Zealand.)—There is little doubt that it constitutes a nuisance.

Mr. Needham is thanked for the newspaper cutting.

Coroners' Inquests.

To the Editor of The Lancet.

Sir,—Will you kindly insert this letter in your next issue, that I may have the opinion of any of your readers on the matter, and I should be glad if you would also yourself express an opinion.

A. B——, multipara, was confined on the 16th ult. of a living child. No medical attendant had been retained, nor had a midwife. However, a midwife was fetched, who arrived about three hours after the child was born, and she removed the placenta. There was considerable loss of blood at the time, estimated at from one to two gallons. The midwife saw her twice during the next few days, and though the woman was not progressing favourably, it was attributed to "weakness," and no demand was made for further advice.

I was called to see the patient on the 25th ult., the tenth day after confinement, when I found her perfectly exsanguine, skin the colour of parchment, pulse 152, and almost moribund. I expressed an opinion to the mother and sister (who nursed her) that the case was hopeless, and that they had been guilty of gross and culpable neglect in not procuring medical aid sooner. The woman died on the 29th, the fourth day of my attendance.

Instead of certifying the cause of death to the registrar (who is an old medical practitioner in the place), I sent him a brief sketch of the case, in substance like the foregoing, concluding by asking him to "decide as to the propriety of an inquiry, or whether a certificate should be given in the usual form." To this he replied, "If you were her only or last medical attendant, it is your duty to state the cause of death on the usual form." This I at once did. Next day I received a note from the surgeon registrar, saying, "I am unwilling to take the responsibility of deciding in the case, and have therefore written to the coroner, enclosing your letter, my answer, and the certificate of death." The coroner replied, "On reading all the letters, I do not think it necessary to hold an inquest."

Now, Sir, the point on which I solicit your opinion is, whether it is not clearly a case in which an inquest should have been held—not to elucidate the cause of death, as that was perfectly clear, but to apportion the blame in such a patent case of neglect; for, as I take it, the woman's life was lost simply from the lack of timely medical aid, and this was virtually admitted by those who nursed her. It also forcibly illustrates the great want of certified midwives, as no doubt many lives are annually lost through the present ignorant female practitioners of the obstetric art.

I am, Sir, your obedient servant,

September, 1875. Fiat Justitia ruat Cœlum.

*** Supposing the above to be a perfectly correct narrative of the facts, we entirely agree with the writer of this letter, and think the coroner was very much at fault in not investigating a case which illustrates the lamentable ignorance of midwives, and the hard case of puerperal women in the poorer ranks of life.—**Ed. L.**

SHIP SURGEONS.

M.D. would be glad to be introduced to a *confrère* in London who has made voyages to the colonies as ship surgeon, and who would kindly give some information which is desired.

Nemo (Liverpool) will find the subject commented on rather fully in our number of August 7th.

ARMY MEDICAL EXAMINATION.

To the Editor of THE LANCET.

SIR,—Allow me to correct an error in your remarks of the 4th inst. relative to the candidates for the A.M.D. examination.

There were 22 candidates. One failed physically, one retired from the examination, 4 failed to pass the qualifying test, and 15 were accepted; of whom one at least did not obtain the number hitherto necessary to pass—viz., 1500, or half the total possible, 3000. The vacancies, as per Army List and Army Estimates, are fully 40. The navy had 3 candidates: one failed, 3 passed, and 3 have been taken who *qualified* for India, but for whom there were not vacancies. For India there were 10 vacancies, 30 candidates, all qualified. What a contrast! Yours truly,

September, 1875. A. M.

A Clinical Lecture
ON
THE PULSE: ITS DIAGNOSTIC, PROGNOSTIC, AND THERAPEUTIC INDICATIONS.

Being Lecture IV. delivered at St. Mary's Hospital in the Summer Session of 1875,

BY W. H. BROADBENT, M.D., F.R.C.P.,
PHYSICIAN TO THE HOSPITAL.

GENTLEMEN,—My lecture to-day cannot strictly be called a clinical one; it is, however, on one of the most important subjects connected with clinical medicine: the pulse—the method of examining it, its mode of production, and the information to be obtained from it.

At every visit to the wards I call your attention to the distinctive characters of the different kinds of pulse, and endeavour to impress upon you the value of the indications, diagnostic, prognostic, and therapeutic, to be derived from these. Not to speak of heart diseases for the moment, some of you have seen, during the present session, a diagnosis of renal disease arrived at simply by placing the fingers on the wrist, reversing a first-sight opinion in the direction of syphilitic disease of cerebellum; prognosis, not otherwise obvious, based on states of pulse—of death, or of incurable condition, or of protracted convalescence, verified by the event; successful treatment by active purgation thus suggested, when the prominent complaint was of great weakness. I propose now to systematise these ward-teachings, and explain the basis on which they are founded.

I have long been in the habit of saying that the examination of the pulse was one of the lost arts till it was restored to us by means of the sphygmograph. It was with astonishment that I learnt, when I first took up the study, that every single element of the pulse revealed to us by the sphygmograph had been previously recognised by the old school of physicians, and that a nomenclature existed ready made for all its teachings. It is maintained that this knowledge has never died out, but that it has been perpetuated as a sort of tradition through a succession of able physicians; but if you look through the records of cases in the medical journals you will find that medical men have usually been content to note the rate of the pulse with the addition of an occasional more or less unmeaning remark as to its character. This was not so with our predecessors, who used carefully to describe the exact character of the pulse as recognised by the finger very much as we now do by the aid of the sphygmograph.

Mode of feeling the pulse.—First, let me speak of the mode of feeling the pulse. Three fingers should be placed lightly upon the radial artery. Attention is first to be directed to the frequency of the beats, remembering always, before forming conclusions, that the rate is liable to be influenced by position, by food or drink recently taken (especially stimulants), by exertion (particularly when the patient is weak), or by emotion or excitement. You will make allowance for these disturbing causes; and when dealing with an excitable, nervous, or weak person, keep your hand on the pulse for some time, conversing perhaps on other symptoms or on indifferent subjects, or you may examine the rate a second time, getting an idea of the frequency before looking at the watch, which, by attracting the patient's attention, may send up the pulse by ten or twenty beats. Of course, while ascertaining the frequency, you would note also the regularity or irregularity of the rhythm.

Next, or at any rate as a separate act of attention, estimate the size of the artery, whether large or small, and the resistance it offers to the fingers. I do not mean here the strength of the pulsation, but the feel of the vessel and its general condition. Carry the fingers along it longitudinally on the one hand, and, on the other, try if it can be rolled transversely like a cord. I shall describe later the indications to be derived from the size of the vessel; but I may just say here that degeneration of the artery is revealed by inequalities felt as the fingers glide along its length, and by a kind of rigidity, or if the artery imparts to the finger somewhat of the sensation of a string of beads; while undue tension is recognised by the cord-like character of the vessel during the intervals between the pulsations.

Finally, you test the strength of the pulsation, which, as I shall explain to you later, may differ greatly from the estimate derived from first impressions. I said you should place three fingers lightly upon the artery; you should now, with the finger nearest the heart, steadily exercise compression, till the wave no longer passes to be felt by the remaining fingers. The pressure should then be repeatedly or continually varied with one, two, or all three fingers—now to complete occlusion of the artery, now a mere touch,—till you form a definite idea of the force with which the blood is being driven.

The pulse: what is it?—We must now analyse the information we obtain by the simple act I have described. But, first, what is it that we feel when our hand is on the pulse? Is it an enlargement in the diameter of the artery? or is it an elongation and curving of the vessel—a locomotion, as it has been called? It is neither. I do not absolutely deny that there is lateral dilatation of the artery, or that it is in some places thrown into curves. That there is some increase in diameter in the large arteries has been demonstrated, and sinuous movements may be seen any day in the temporal arteries of an old person; but this is not what we feel, nor what the sphygmograph records. To feel the pulsation in an artery, or to take a sphygmographic trace, pressure must be applied to it; and, as you all know, we must have a bone behind it against which it can be compressed. In the intervals between the pulsations, when the internal tension or pressure by the contained blood is at its lowest, we flatten the tube of the artery more or less; then comes the wave of blood and forces, or tries to force, the vessel back to its cylindrical form; *and this change of shape from the flattened form impressed upon it by pressure, to the round condition which it assumes under the distending force of the blood within it, constitutes for us the pulse.* Such a pulse can be felt on a larger scale by the foot placed upon the leathern hose of a fire-engine in action, which, I need scarcely say, exhibits no increase of diameter or serpentine motion. This explanation is important.

Factors of the pulse. — There are three factors in the production of the pulse, and of the different modifications of it which we find in practice; and we shall only fully estimate the significance of these modifications by referring them to their respective causes. These three factors are (1) the action of the heart, (2) the degree of resistance to the passage of the blood through the capillaries and arterioles, and (3) the elasticity of the large arteries. On the action of the heart will depend the rate, rhythm, and force, or, in other words, the frequency, regularity or irregularity, and strength of the pulse. On the degree of contraction of the arterioles and the amount of resistance offered to the free passage of the blood by them and the capillaries will depend the size of the radial artery and the blood-pressure within it—in other words, the character of the pulse, whether large, short (or quick), and soft, or small, long, and hard. On the elasticity of the great vessels will depend other modifications; to each of them we must devote a few moments' consideration.

Frequency. — The heart, then, may act frequently or infrequently, regularly or irregularly; and its contractions may be abrupt and rapid, or slow and deliberate—strong, again, or weak. The frequency of the heart's action is under the control of the nervous system. Physiological experiments have taught us that the heart has a system of ganglia of its own, on which its action immediately depends; but that the sympathetic is an excitor, the pneumogastric a controller or inhibitor, of the heart. As yet we cannot apply this knowledge clinically in any important degree, as it is to be hoped we shall some day do, but only reason backwards, so to speak, and say that under given circumstances the sympathetic or pneumogastric is stimulated or paralysed, because the action of the heart is rapid or slow. We need not therefore dwell on these physiological details, but simply mention the more important clinical indications of the pulse-rate. It is not often that is rendered much slower than the normal rate for the individual by disease.*

---

* This rate, as is well known, varies greatly, 72 beats per minute being the average for adult healthy males. It is more frequent in women of about eighty, and especially in children. But a pulse of 60 is often met with; sometimes perhaps of 40 or even less, or, on the other hand, of 90 or 100.

In jaundice this is sometimes the case. In the intervals of relapsing fever, in the later stages of meningitis, and notably in some instances of fatty degeneration of the heart, slowing of the pulse is met with; so also in some affections of the nervous system. But I do not know that there is much on which I need dwell. Increased frequency is infinitely more common; and, indeed, disturbing influences of whatever kind are attended with this result. Such apparently opposite conditions as pyrexia and debility alike render the pulse frequent. We have no right, perhaps, to put pyrexia and asthenia into contrast, but still they affect the pulse-rate in a different way. Pyrexia, for instance, neutralises to some extent, debility exaggerates, the effect of change from the standing to the recumbent posture.

In pyrexial diseases the pulse-rate is, as I have said, raised, and sometimes the mere frequency has great significance. It has been said to indicate the "alarm" of the nervous system at the attack; and when this expression of "alarm" or "apprehension" of the nervous system is unusually emphatic, we may be sure that the constitution has been staggered by the blow. At the onset of a fever, of whatever kind, a sustained frequency above the rate usual at that stage of the particular fever may be a long way in advance of other unfavourable prognostic indications, which, in most cases, will inevitably follow. When the pulse and temperature are apparently in contradiction, the excessively frequent pulse threatening danger, which is not borne out by excessively high temperature, it is the pulse which we must take as our guide in prognosis. On the other hand, a very high temperature would be a mark of danger independently of excessive frequency of pulse. Usually, however, the pulse and temperature coincide in their indications. It is, perhaps, in puerperal affections that this racing pulse most frequently gives the alarm, while as yet other symptoms have not assumed a serious character. Sometimes, again, an exceedingly rapid and at the same time weak pulse is the most striking feature of an early stage of collapse, and gives the first alarm. In pneumonia a rapid pulse is always indicative of danger, even though the extent of lung involved may not be considerable.

Unnaturally rapid and violent action of the heart for a short time is extremely common, and is known as palpitation. Its significance is very different in different cases; but usually it is of no great consequence. It is a familiar observation that the patients who come to us complaining of the heart, of uneasy sensations or pain in it, or of palpitation, are rarely suffering from heart disease. Nervous and weak people, women especially, suffer from palpitation on the slightest provocation. An emotion, a little exertion, flatulence, or food may set it up; or the heart may suddenly start off without any apparent cause, sometimes during sleep. Gouty and dyspeptic subjects, again, are liable to palpitation. Usually attacks of palpitation are of no long duration, but at times we meet with instances in which the unnaturally rapid action goes on for twenty-four hours or more. Dr. Farquharson has lately contributed an interesting article on this subject to the medical journals. I have also met with several similar cases. Not long ago I was asked to see a lady's maid, who was supposed to be suffering from some sudden affection of the lungs; she was sitting up in bed, with a pale and anxious face, almost gasping for breath, and from time to time coughing a single short cough. Placing my finger on the pulse I found the radial artery persistently full; but the only pulsation to be felt in it was an occasional feeble beat, or rapid succession of several such weak, small beats, followed by a pause. When I came to examine the heart, however, it was beating at the rate of nearly 200 a minute, regularly and equably, but somewhat feebly, which was not to be wondered at, as the attack had already lasted more than twelve hours. This rapid action kept the artery at the wrist full of blood; but few of the individual pulsations reached this vessel, either because they were too weak, or more probably because the brief diastole afforded no time for blood to enter the left ventricle. The usual heart-sounds were not to be distinguished; what was heard was a rapid series of short puffs, reminding me of the sound of a distant locomotive. There was nothing the matter with the lungs; the attack had been induced by over-exertion. I gave belladonna, with ammonia and ether, and the excitement of the heart gradually subsided in the course of another twenty-four hours, and it was then seen that there was no heart disease. The patient was very much shaken, and it was long before she was able to resume her work. I have seen several such cases. In one in which mitral disease was complicated by a tendency to attacks of this kind, the patient would lie insensible for hours while the palpitation lasted, the pupils being dilated and insensible to light. I do not propose to enter minutely on the indications of increased frequency of the pulse. The pulse-rate is universally noted, and receives adequate attention; and I wish to call attention more particularly to the features of the pulse which are less obvious and more neglected.

Rhythm of pulse.—Usually the pulse is regular, and the beats equal in force and at equal intervals. Departures from this rule, however, are not uncommon. They are of two kinds: intermittence and irregularity.

Intermittent pulse.—The rhythm, otherwise equal, may be broken by the occasional omission of a beat—an *intermission.* Frequently the intermission is perfectly regular, a pulsation being missing every fourth, or tenth, or twentieth beat; but sometimes we have, say, ten or twenty beats, then an intermission, and very soon another. When the intermissions are frequent—i. e., every four or six beats—they are more likely to be regular. The most remarkable instance I ever met with was in a man fifty years of age, who had two pulsations and then two intermissions. When counting the pulse, it occurred as one, two beats, then one, two intermissions. The man went out of the hospital in two or three days, to my great regret, and I was unable to make a careful investigation of the case. Intermission of the pulse is rare in young people, and I should think more seriously of it early in life. After middle age it is not uncommon; in some cases it is habitual, in others occasional only, and induced by dyspepsia, constipation, smoking, drinking, &c. One patient of mine has intermittent action of the heart produced by a particular kind of tea, another by a particular brand of cigars. Some patients are entirely unconscious of the intermissions, especially those in whom it is habitual; others feel as if the heart rolled over or stopped, and are made uncomfortable. Although the pulse is absent at the wrist, the heart's action is not usually absolutely suspended; on listening, an imperfect beat can be heard just after the last proper beat, the sounds audible being a feeble first sound and a weak pulmonary second sound. The aortic second sound is usually absent, as if the pressure in the left ventricle had been insufficient to raise the valves, while in the pulmonary artery, where the resistance is less, some little blood appears to pass.

Intermission of the heart's action is usually attributed to some affection of its innervation, and the chief cause is, according to Dr. B. W. Richardson, shock, anxiety, or grief. The subjects of this affection are apparently none the worse for it, and I have met with it in many hale old men long past the usual term of life, and some have said they have had an intermittent pulse for very many years. Still it is stated that, though equal to the ordinary occasions of life, they break down more readily, and withstand attacks of disease badly. An intermittent pulse does not contraindicate chloroform; I have often known the intermittence disappear during its administration. I am speaking always of those cases in which an intermittent pulse is not a symptom of disease in the walls of the heart, of which there are other indications.

Irregularity of pulse.—The other form or kind of departure from the normal rhythmic action of the heart is generally called irregularity: the pulse is irregular both in force and frequency; the beats are unequal in strength, and follow each other at irregular intervals. The most common and striking instances of irregularity are those resulting from mitral regurgitation. In fact, this is the condition which of all others is attended with irregular pulse. Other diseases of the heart, whether of its walls or valves, give rise to conspicuous irregularity of the pulse only when the heart is failing or when it is tried by some pulmonary or other complication; but in mitral regurgitation it goes on for years. I do not know that there is any generally accepted explanation of this, but we may seek one by the method of exclusion. The irregularity of the pulse cannot, then, be due to any structural change or functional weakness of the walls of the heart or to any derangement of the cardiac innervation, or it would accompany other heart diseases. It cannot, again, be due to simply the influence on the dilated right ventricle of the respiratory movements, or it would occur in mitral constriction, in which the right ventricle is also dilated. One cause, no doubt, is the variable amount of blood which escapes back into the auricle, or, rather, which the ventricle finds to propel into the aorta: in one systole the valves get better into position, or they are backed by good pressure in the auricle and pulmonary veins, the ventricle meets with a due degree of resistance and sends on its contents into the systemic arteries; in another, for some reason or other, the regurgitation is considerable, the ventricle has no work to do, is disappointed, contracts hurriedly, and is thrown out of step. But I am disposed ultimately to attribute it, more than to anything else, to the varying pressure on the dilated left auricle during respiration; more particularly to the negative pressure or suction action on this auricle in inspiration preventing it from contracting fully and carrying its blood on into the ventricle. But I ask myself, why have we not the same result in mitral obstruction, when the auricle is even more dilated; or in tricuspid regurgitation, when the right auricle and ventricle are similarly situated? The explanation is incomplete unless we can answer this question. I shall consider this more fully on some other occasion, but I may say briefly that an answer is to be found in the difference between the steady pressure in the pulmonary veins and left auricle in mitral constriction and the fluctuating pressure in regurgitation, and again in the fact that the right auricle receives veins from outside the chest, and during inspiratory suction fills itself from them, while the pulmonary veins, as well as the left auricle, and even in a greater degree, are exposed to the negative pressure of the active inspiration.

That the action of the heart is greatly influenced by the respiratory movements is well known, and can be made evident at any time by taking a deep inspiration or by holding the breath; and the nearest imitation of mitral irregularity of the pulse is met with in bronchitis and emphysema, in which respiration is laboured.

Other conditions attended with irregularity of the pulse are some affections of the nervous system.

Force or strength of pulse.—As to the strength of the pulse, I have told you how it is to be estimated. It is of course entirely dependent on the force of the heart's action, but the apparent strength is greatly modified by the condition of the artery. If the walls of the vessel are relaxed, its calibre is enlarged, and at the same time the general tension or blood-pressure within it is low, so that in the intervals the artery is easily flattened by the finger; under these conditions the sudden filling of the large vessel gives the impression of a very forcible pulsation, which may sometimes be corrected or reversed by finding that it is easily extinguished by pressure. On the other hand, if the artery is contracted and small, the tension will be high; it will not be flattened by the degree of pressure usually applied in feeling the pulse; the pulsation therefore will be comparatively slight; but let the attempt be made to extinguish it, and the real strength will become apparent. It is of the greatest importance that you should be alive to this.

There are circumstances in which the pulse is really feeble, and not apparently so merely, while the heart is beating with great force, and this quite independently of disease of the valves. For instance, in pneumonia or bronchitis there is often so much obstruction to the pulmonary circulation that the blood does not reach the left ventricle in proper quantity, and a forcible contraction of the ventricle has no effect on the arterial system, unless there is blood to be expelled; the pulse therefore is weak and small, and the face pale, while the action of the heart is very powerful. A similar result is sometimes produced by mere excessive frequency of the heart's action: the diastole is so short that the ventricles have not time to fill, and cannot therefore send on blood.

One more point with respect to the action of the heart. This may be deliberate or sudden. I have avoided the use of the terms "slow" and "quick" in speaking of rates of pulse, because they have a double application—to the mode as well as to the frequency of the heart's contraction; whether, that is, the contraction is deliberate, and occupies an appreciable time, on the one hand, or is swift and soon completed, on the other; or, in other terms, to the character as well as to the rate of the pulse—whether, namely, this is long, and lingers under the finger, or short, sudden, and gone immediately. The heart, of course, contracts with very different force at different times, but, the force it exerts being equal, the gradual or abrupt character of the contraction will depend entirely on the resistance it has to overcome. If this is considerable, the contraction is steady; if very slight, it is abrupt. Now the resistance is determined by the state of the peripheral arterioles, and we are coming to the consideration of this—the second great factor of the pulse.

Condition of arterioles as a factor of pulse.—You are all aware that the function of the arterioles is to regulate the blood-supply to individual parts. This it does by means of the muscular fibres in the walls of the minute bloodvessels; and under the influence of the sympathetic nerve, which is the motor nerve of these fibres, you have the muscular walls contracting and narrowing the vessels. There is also said to be an active dilatation of these vessels, not mere distension. Now not only are particular arteries relaxed or contracted, but at times general relaxation or contraction of all the vessels throughout the body occurs, though dilatation of one very large arterial area will affect the general blood tension; as, for example, of the gastro-hepatic system, after taking food, when the blood-pressure throughout the body is reduced. You will easily see the effect of dilatation or contraction of these minute arteries on the pulse. When the muscular walls of the vessels are in a state of relaxation the diameter is increased, and the pulse feels *large*. The blood is more easily and quickly propelled through a wide tube; the pulse is therefore *quick* or *short*. Finally, there being little resistance, there can be no sustained pressure; you have low arterial tension, the pulse is therefore *soft*.

If the vessels be contracted, the converse occurs in each particular: the artery feels contracted—that is, *small*,—the blood takes a longer time to travel through it, and remains longer under the finger; the pulse is, therefore, called *long*. The resistance to the passage of the blood requires high pressure for its propulsion; the pulse is, therefore, *hard*. By arterial tension or intravascular pressure is meant the pressure of the blood on the walls of the containing vessels, or the distending force within the vessels. The characteristics of a pulse of high tension are that it is small, long, and hard. But, before the pulse can be studied as a whole, the elasticity of the walls of the large arteries must also be taken into account. This equalises the blood-stream, and promotes the flow. We may illustrate this by a simple experiment:—Take two tubes, the one rigid and the other elastic. If now water be pumped through them in intermitting jets, it will issue from the rigid tube in a similar manner to that in which it entered it—namely, by jets; while from the elastic tube it will flow in an unintermitting though pulsatile stream, and a larger amount of fluid will pass in a given time. Other less obvious modifications of the pulse will best be illustrated by means of sphygmographic tracings, which we shall briefly consider in the next lecture.

BEQUESTS, &C., TO MEDICAL CHARITIES.—Mr. Richard Minter Mount, of Wingham, bequeathed £10,000 to the Kent County Ophthalmic Hospital, Maidstone, £100 to the Kent and Canterbury Hospital, £100 to the Canterbury Dispensary, and the "residue" of his estate to the Royal South London Ophthalmic Hospital. Mr. Thomas Bless Pugh, of Clapham-road, bequeathed £3000 to the Royal Sea-Bathing Infirmary, Margate, £300 to the London Fever Hospital, £300 to the Samaritan Society of St. Thomas's Hospital, and £10,000 Consols, at the death of his wife, to the Medical Benevolent College at Epsom, for the creation of pensioners to receive annuities without residence. The Rev. Henry Charles Morgan, of Goodrich, Herefordshire, and Oakfield, Berkshire, bequeathed £1000 each to the Royal Berkshire Hospital, the North London Consumption Hospital, University College Hospital, Middlesex Hospital, London Hospital, St. Mary's Hospital, St. George's Hospital, Queen Charlotte's Lying-in Hospital, Lock Hospital, Westminster Hospital, King's College Hospital, Royal London Ophthalmic Hospital, Earlswood Asylum for Idiots, Hereford Infirmary, Society for the Relief of Widows and Orphans of Medical Men, and the Ross Dispensary; and £100 to the Metropolitan Free Hospital, Devonshire-square. Mr. John Spriggs Morss Churchill, of Pembridge-square, bequeathed £500 each to the Royal Medical Benevolent College at Epsom and the Medical Benevolent Fund.

Clinical Lecture
ON
SOFT CHANCRES IN THEIR RELATION TO SYPHILIS.

By JONATHAN HUTCHINSON, F.R.C.S.,
SENIOR SURGEON TO THE LONDON HOSPITAL,
SURGEON TO MOORFIELDS OPHTHALMIC HOSPITAL AND TO THE HOSPITAL FOR SKIN DISEASES.

(*Concluded from page* 410.)

Amongst the important practical questions which are connected with this subject we have chiefly—1st, At what period in the course of a chancre can the surgeon venture an opinion as to its nature? 2ndly, Are the characters of the two forms of chancre, soft and hard, often mixed? And 3rdly, Can a chancre which presented at one stage all the characters of a soft one subsequently become indurated? If I have made my meaning clear in what I have already said, you will be at no loss to find an answer to these questions. My position is that the soft sore results simply from pus-contagion, this pus being more or less peculiar, and its peculiarities being due to its having originated in syphilitic inflammation. I have insisted that this pus may or may not contain the germ-matter of syphilis. We are therefore much in the position of a farmer who sows in his field two seeds mixed together of very different rates of germinating power—clover and barley, for instance. The one which grows quickest is the one which first attracts attention, and it may be that one conceals the other. So it is if the fluid which conveys syphilis be an admixture of contagious pus and the specific germs of the true disease. The pus will irritate directly; the syphilitic germs need their period of incubation. Thus you will have first an inflamed pus-secreting ulcer, entirely free from induration. This may go through its course and heal, and then, at the end of a month, when the syphilis-incubation period is past, you may find proof in the induration which comes on that another and wholly different kind of seed had been sown at the same time. It is much the same as with the farmer when he cuts down his barley and finds the clover growing at the bottom. I might carry this agricultural simile yet further, and might remind you that if the barley has been particularly heavy, if it has been laid and matted, it may kill the clover altogether. It is just so when a contagion of mixed material occurs in syphilis. If the soft sore is a very bad one—or perhaps I ought to use the reverse epithet,—it may altogether destroy the germs of the other poison which were implanted with it. Probably in this way many a soft sore does really prevent the development of a hard one. In practice, however, this happy result is by no means universal, and it is a very common event to see a transitory soft sore followed by specific induration.

Let me here insist upon the extreme importance to the reputation of the practitioner of the rule never to give an opinion as to the nature of a chancre until the incubation period is over. Patients will come to you with sores contracted a few days or a week or two before, and will expect you to be able to tell them whether or not they are likely to have syphilis. Now, there is never anything in the conditions which are either present or absent which will justify the most practised observer in giving any opinion at such a stage. It is very rare indeed that an infecting sore acquires any induration within three weeks of the date of contagion, and more commonly it is a month or five weeks. Until such induration takes place, nobody can tell whether it is coming or not.

Very various indeed are the conditions which may have been present during the preceding period. Your patient may have had a soft sore, which may have been severely inflamed, or even phagedænic; he may have had a bubo, and that bubo may have suppurated; or he may have had no sore at all, and no bubo. Let your rule be, I repeat, to give to your patient no opinion whatever as to his chance of escape until he can assure you that it is one month since his last exposure to risk. It is a matter of constant experience to be told by patients that the medical man first consulted assured them that the sore was only a soft one, and would not infect; and, under such circumstances, it is always very difficult to restore the patient's confidence in his adviser's knowledge. If the contagion of syphilis were always effected with the same care as to purity of the virus as is exercised in the case of selection of lymph for vaccination, it would not have been necessary to teach this doctrine of caution now. No one thinks of speaking as to the prospect of the success of vaccination during the first few days, nor would he be able to do so even so soon as that were it not that the vaccine vesicle is enabled to develop itself uncomplicated by other morbid processes. It is not so, however, with syphilis, and hence the variety of the results which we witness during the first two or three weeks after contagion. If the virus be introduced in a pure, or almost pure, state, then it is probable that in many cases the patient experiences nothing excepting, perhaps for a few days, a little red pimple, which disappears, and leaves him, as he thinks, quite well for another three weeks or a month. At the end of that time the part begins to itch a little, and again becomes red, and gradually within a week or so a well-characterised induration is developed. If, however, the contagion have been effected by a mixture of contagious pus and specific virus, then you have a very different course of things. Within the first few days the contaminated part may inflame sharply, and an ulcer may result which will probably send the patient in great alarm to his surgeon. This sore is, of course, soft; it secretes freely, and its secretion may contaminate other parts, and you may have what are termed multiple soft chancres. You may inoculate it, if wished, on the patient's skin, and produce other similar sores, and thus prove that you have to do with a non-specific secretion. But all this does not prove that the specific poison is not there, and whatever may be the course of these soft sores, whether easy to heal or obstinate, there remains the risk that specific induration may ultimately be developed. Probably the worse the sore, the more the inflammation, and the deeper the ulceration, the greater is the patient's chance that the specific virus may be thrown off; whilst if the sore heals in a few days the danger of true syphilis is considerable. We often, from patients who are the subjects of tertiary disease, hear the statement that the original sore healed in a week, and gave scarcely any trouble. Such cases are, I suspect, examples of the early healing of a conspicuous soft sore, which was followed some weeks later by an inconspicuous and unobserved hard one. Should the soft sore, however, be of protracted duration, it is, I suppose, possible that its characters may extend over the whole period of induration proper to the specific one. Under these circumstances the characters of the specific sore may be masked, and even good observers may never have been able to detect the characters of specificity in sores which yet proved infecting. At any rate, I am sure that you must be prepared to find that occasionally syphilis will follow from sores which you have had frequent opportunities of examining, and which from beginning to end you had thought to be soft and suppurative. If the sore should not only ulcerate, but become phagedænic, it is then usually quite impossible to diagnose induration; yet, under such circumstances, secondary symptoms often, or indeed usually, follow.

If the argument which I have used be correct, it follows that whenever you detect induration you will be certain that constitutional syphilis will follow, but that, however sure you may be of the absence of induration, you can entertain no security unless a long period has elapsed. You will ask, naturally, If this be so, would it not be well, bearing in mind the very serious consequences which syphilis entails, to deal with all soft chancres as if they were infecting ones? Candidly, my belief is that there would be great wisdom in adopting this rule, at any rate so far as local applications are concerned. In very many cases I have no doubt that the soft sore occurs exactly over the site of a coming induration; and should your patient consult you within a reasonable period of the exposure to contagion, I cannot but think that it is good practice to destroy it by deep and free cauterisation, rather than to attempt merely to make it heal. Some of the published records of attempts at abortive cauterisation of chancres prove that it is not possible in all cases to prevent the subsequent development of induration; but a few failures of this kind by no means make it certain that the practice would not be productive of good results in the long run. It might fail sometimes and succeed sometimes. It unfortunately happens that we should know when we failed, and should never know when we succeeded. It is very difficult, however, to believe that the progress of imbibition of the syphilitic virus is so rapid that there is no stage during which it exists only in the contaminated spot. How long this stage may be it is exceedingly difficult to tell, but for the present I cannot but think that it is wise to act as if it comprised the first week or ten days after inoculation. I have been alluding hitherto only to treatment with the object of utterly destroying by cauterisation the portion of tissue in which the poison is suspected to lurk; but there remains the question as to how early we ought to attack the virus by its antidote. It is, I am glad to believe, becoming increasingly the rule of English practice to give mercury as soon as ever specific induration can be recognised; but it is quite possible that we may, in the future, go further than this, and think that it is best to prescribe this remedy for all sores occurring within a month of contagion. We should no longer do so under the impression which formerly prevailed, that it was necessary in order to make the sore heal, for we now know that the soft sore is not syphilis, and cannot be influenced by its specific. The reason for giving it would be the fear that the patient may be passing unnoticed through the incubation stage of a true chancre. The soft sore proves that he has been contaminated with venereal pus, and shows that it is not improbable that he may have received the syphilitic virus also. It is quite possible that the antidotal efficacy of mercury may be much greater in the early stage than in the later ones. I wish, however, to have it distinctly understood for the present that I am merely suggesting, and not recommending. I am often pressed by patients to allow them to take mercury on speculation for soft sores, but hitherto have for the most part declined to do it; my reason being, that until some proof has been afforded that we have to deal with true syphilis, we have no data by which to determine the requisite length of treatment.

THE

TREATMENT OF SECONDARY AFFECTIONS OF THE HEART.

By J. MILNER FOTHERGILL, M.D., M.R.C.P.,
JUNIOR PHYSICIAN TO THE WEST LONDON HOSPITAL.

THIS class of affections of the heart is a very large one, becoming of more and more importance as the power to recognise such affections enlarges. This form of heart ailment, for it is not strictly correct to term it "heart disease," is largely found in persons of advanced life. It is this class of affections which has been found so intractable to the well-worn remedial measures ordinarily in use. The consequences of such measures usually were very unsatisfactory; often, indeed, the results of treatment were a condition more intolerable than the primitive one for which relief was sought. That such should be the case is in no wise incomprehensible when we reflect upon the very imperfect physiological knowledge of most practitioners; and when we consider how physiology held the only key which would unlock the approach to a knowledge of how the heart could be affected secondarily, and how accordingly the plan of treatment was to be directed.

It is not the writer's intention to allude in this place to genuine neurosal affections of the heart. In order to make clear what secondary affections of the heart are, it will be necessary to review briefly some points in connexion with the circulation. The heart in its contraction, or rather in the contraction of the ventricles, and more especially the left ventricle, has to overcome the resistance offered to its contraction by the fluid contents of the arteries. If the arteries are tensely filled with blood a more powerful ventricular contraction is required to force the blood from the ventricle into the arteries than is necessitated when the arteries are comparatively unfilled. This is intelligible enough; it would be surprising if it were not so. Conditions of sustained high arterial tension usually result in hypertrophy of the left ventricle, as is seen so commonly in chronic Bright's disease. Under these circumstances the hypertrophy is not a disease—it is a compensatory growth; and it is a fortunate circumstance for the patient that such growth is set up. Unfortunately, however, some confusion exists on this matter, and one man regards this hypertrophy as a disease, and speaks of it as such, while another has learned to recognise in it a conservative growth by which the patient's existence may be prolonged, and consequently he neither regards it nor speaks of it as a disease. This apparent antagonism of medical opinions is often very perplexing to the patient, and it is very desirable that a more distinct understanding should exist on this matter. If the different medical gentlemen could only have an opportunity of talking the matter over together, the apparent contradiction would vanish, and this result would be very acceptable to the patient.

Where such hypertrophy exists in good degree, the rule is that the patient does not feel ill, and consequently does not consult the profession. At other times the heart is unequal to the demands upon it, and consequently falters. Then the patient goes to a medical man for aid. If the resistance offered by the blood already in the arterial system is greater at one time than another, then there usually results a condition of matters of this kind: at times the heart is equal to the successful overcoming of the resistance offered to the ventricular contraction, and the patient feels well; at other times the heart is not equal to the effort required, and then palpitation, a laborious effort, or irregularity in the heart's action is induced, which alarms the patient and leads to his consulting his medical man. If the true state of matters be not recognised, that consultation will be of small avail to the patient.

It is obvious enough that under these circumstances the heart is not primarily at fault, and that the correct treatment is not to spur on the heart, but to relieve the condition which causes the heart to give evidences of lack of capacity. In order, however, that this may be done, it is absolutely requisite to bear in mind clearly the physiology of the circulation. The heart is a hollow muscle which, by its contraction, throws a certain quantity of blood rhythmically into the elastic arterial system. By virtue of its elasticity, the arterial system maintains a steady flow in the smaller peripheral vessels. All arteries contain muscular fibre; in the large vessels the muscular fibre is present in but small proportion; in the smaller vessels the wall is comparatively muscular. By contraction of the muscular walls of these smaller vessels their lumen is diminished, the blood-flow through them is obstructed, and then the blood-pressure in the larger vessels rises,—in other words, there is an increase of arterial tension, and then the heart is involved; the ventricle must either contract more powerfully or the heart is embarrassed. If the ventricle is equal to the demand upon it all is well, and the person is unconscious of the working of his heart; if not quite equal to the demand, the heart's action will probably attract the attention of the individual.

It is only within the last few years that we have known anything accurate about arterial tension. We were all familiar with the firm, incompressible pulse of well-filled arteries, and the slow steady action of the heart which accompanies this condition in health; and also the opposite condition of unfilled, easily-compressible arteries, with the fast action of the heart which goes along with this state of matters. More recently, however, the invention of the sphygmograph has rendered the varying condition of the vascular system more demonstrable, and even written them on enduring tracings. These tracings are not mere matters of curiosity. They form ocular demonstrations of the condition of the arterial system; they are faithful witnesses of the actual state of matters, and their testimony undergoes no impairment of accuracy by time—there is no traitorous memory to fear in their case. In 1866 Dr. Lauder Brunton observed, by means of the sphygmograph, that during an attack of angina pectoris the blood-pressure rose. Hitherto this terrible affection had been regarded as a primary failure in the heart itself. All the remedial measures usually employed in these cases were tried, and proved simply useless, and the man was about to leave the Edinburgh Royal Infirmary unrelieved, when a bright thought crossed Dr. Brunton's mind. He bethought him that experimental research had revealed an agent which dilated the arteries, and especially the small terminal arterioles. Theoretically, this agent should counteract the arteriole contraction, on which the increased arterial tension rested, and so relieve the embarrassed heart. The result demonstrated the correctness of the inference, and the dreadful attack was at once shorn of its terrors. This beautiful practical application of knowledge, reached by physiological experiment, attracted at once the attention of the late Dr. Anstie, and he tried this remedy in a similar case with like results. This correct synthesis erected by Dr. Brunton has opened up a much wider field in the territory of therapeutics than was ever anticipated by him at the time. Not only is nitrite of amyl—as this agent is termed—achieving great results for itself, but it has pointed out a new direction, a new line of practice, for the successful treatment of a very large class of affections of the vascular system. The relief of an embarrassed heart by abolishing the condition of the terminal vessels by which this embarrassment was brought about, was the foundation-stone of what promises to be a goodly therapeutic structure.

It has long been known that hypertrophy of the left ventricle was very common in chronic Bright's disease, and that in such cases the muscular wall of the arterioles was also thickened. The researches of Johnson, Traube, and Grainger Stewart have established this beyond dispute. The obstruction offered to the blood-flow by these hypertrophied arterioles stands in a causal relationship to the ventricular hypertrophy. Not only so, but a rise in arterial tension is found to be the cause of much disturbance in the heart. Especially is this the case in persons of middle age and of advanced life. It is in them that we find the true angina pectoris—not mere neurosal angina,—whether in its fully developed or in its imperfect forms. Its fully developed form is a comparatively rare but well-marked disease; its imperfect forms are very frequent, variable, and more or less obscure affections. What is practically worse, these forms of imperfect angina are but badly understood, and, from their rooted antipathy to the study of physiology, many practitioners are even unaware of the actual existence of such conditions of the vascular system. Having once learned to recognise the forms of the affections of the heart dependent upon increased arterial tension, their detection and the appropriate treatment suited to them become easy and effective. Cases that before were intractable and unintelligible are now recognisable, and consequently can be beneficially treated. It has been found that to spur on the heart in these conditions by digitalis and iron produces a hammering action of the heart—an additional cause of distress—in many cases, while in a few or none is relief experienced. As a matter of fact, it is not good treatment in such cases to approach the heart first, but rather to reach it indirectly by removing the condition of the arterial system which embarrasses the heart. Once remove the abnormal condition in the peripheral vessels, and then the blood-pressure in the arteries falls and the heart is relieved.

The conditions under which abnormal arterial tension is produced are chiefly those of lithiasis and hysterical spasm of the arterioles. A low temperature produces an increased arterial tension from the contraction of the cutaneous vessels. This was well seen in a patient of mine at the West London Hospital, who suffers from aneurism of the ascending aorta. He observed himself that during the cold weather of last Christmas the tumour was more prominent, and the pulsation more distinct; while in the warmer weather which followed, the aneurism was quieter, less prominent, and its pulsations calmer. When there is a rise in the arterial tension, the heart will be less or more embarrassed according to the amount of the rise on the one hand, and the condition of the heart on the other. If the rise be great, even a strong and hypertrophied heart will palpitate and give out active evidences of its incapacity to cope successfully with the increased obstruction to be overcome at each systole. If it be small, the strong heart will not render its owner conscious of what is going on. But if that heart be but hypertrophied to a slight degree only, the lesser rises of arterial tension will embarrass it; if there be no hypertrophy, and the heart be feeble or dilated, slight rises, like slight efforts, will call out evidences of cardiac adynamy. It is obvious that betwixt the two extremes a multitude of combinations is possible, and, as a consequence, each case has to be carefully appraised as to its different factors, after it has been relegated to a certain class. This it is, in these cases, which tests the knowledge of the medical attendant—firstly, as to his general acquaintance with this class of ailments; and, secondly, as to his capacity to estimate the exact requirements of each individual case.*

It also does not follow that in chronic Bright's disease there is necessarily a purely hypertrophied left ventricle, especially in women; in them it commonly happens that there is a tendency to dilatation. Consequently, when there is any accumulation of nitrogenised waste in the blood, producing arteriole spasm and a heightened blood-pressure within the arteries, there are evidences of cardiac embarrassment present. When there is genuine hypertrophy of the left ventricle there is usually good general health, fair and often great capacity for exertion, an atheromatous condition of the arteries—a slow and gradual pathological change,—and a liability to apoplexy from the high arterial tension rupturing the thin-walled cerebral vessels. In these cases the heart only becomes an object of attention after fatty degeneration of its structure has cut down the capacity furnished by the hypertrophy, and that is in the later stages of the malady. But when there is not genuine hypertrophy, but only a combination of hypertrophy and dilatation, in various proportions, the cardiac complications often attract attention, and call for treatment. These cases form a large proportion of the cases of heart trouble in persons at or over middle age which we are called upon to treat; and, for successful treatment, it is absolutely necessary that the exact pathological condition be recognised, and the indications for treatment so furnished be correctly estimated.

(To be concluded.)

CONTRIBUTIONS TO AURAL SURGERY.

AURAL SURGEON TO ST. GEORGE'S HOSPITAL.

No. II.—ACCIDENTS TO THE EAR.

(Continued from vol. i., p. 753.)

An account of accidental rupture of the tympanic membrane would be incomplete if mention were not made of this injury as a very frequent result of injudicious attempts which are at times made to extract a foreign body from the external auditory meatus. Any out-patient room devoted to affections of the ear, and every-day experience, will afford ample evidence of the occurrence of such mishaps.

When a child has, or is believed to have, a cherry-stone, a bead, a piece of slate-pencil, a stone, or what not, in the ear, the proceeding which is commonly adopted to effect its removal consists in laying the child down on the side opposite the ear to be operated upon, and some sort of forceps or other instrument ingeniously constructed for the purpose is pushed into the meatus with the well-meant intention of seizing the foreign body and withdrawing it. What then often happens is this. The foreign body, not being immediately captured, on the first touch of the instrument slips down the deep curve which the floor of the bony part of the meatus takes in the direction of the tympanic membrane. A little further groping in the dark now readily ruptures the membrane, and this may be, and often is, effected at leisure if the patient is placed under chloroform; for, inasmuch as the process is extremely painful, it is found that he or she will not submit without so much struggling as to be embarrassing to the operator. The oozing of blood from the meatus will show that the membrane has given way, and in the course of a few days this is still further evinced by the appearance of a purulent discharge from the ear.

---

* The widely different prognosis in various conditions of hypertrophy and dilatation—where the objective symptoms are alike,—according to the accompanying general conditions, was shown in a communication by the writer to The Lancet in May (16th and 30th), and June (6th), 1874.

The frequency of such *accidents* (if such a term is applicable) may be gathered from the fact that during the past session, out of five cases which applied on two successive out-patient days at St. George's Hospital, three on one day and two on the other, the course of events had taken place in the manner described in four. In the first, a small stone had been pushed through the membrane into the tympanum during the course of four attempts which had been made to remove it, two without chloroform and two with. In the second case, a bead had been pushed through the tympanic membrane. In both instances the meatus was very much swollen, there was a purulent discharge from the ear, and in the course of three weeks, when the swelling had subsided, and the ears had been daily syringed by the children's mothers, the stone and bead respectively came out, leaving of course considerable deafness. In the third case, where no attempt had been made to remove it, whilst light was reflected through the speculum, a stone was seen and readily removed with a small pair of ring polypus forceps. In the fourth and fifth cases there was no foreign body in the ear, but the account given by the children and their parents had been thought sufficient to justify interference, which was followed, of course, by a result similar to that which had occurred in the first and second cases. Numbers of such examples might be brought forward, but these will suffice to show how exceptional it must have been for the past generation of students to be taught a simple and ready mode of examination of the external auditory canal. Such an explanation of the *accidents* here mentioned can be the only one admissible, for it is otherwise inconceivable that such surgery could be possible in the present day.

In connexion with this subject, it cannot be too forcibly impressed on the minds of students that by the help of an ordinary ear speculum and an eight-inch focus reflector, the entire meatus and tympanic membrane can be so illuminated that the presence or not of a foreign body may be demonstrated beyond doubt, and that no attempt whatever to remove it should be made unless the canal is at the time thoroughly exposed to the sight of the operator by means of a similar reflector fastened to his forehead by a band round the head—in fact, a laryngoscopic mirror. With this precaution, and ordinary care in the handling of any instrument, the rupture of the tympanic membrane or other injury should be impossible; and, inasmuch as all manipulations should be painless, an anæsthetic becomes necessary only in the case of very young children in order to ensure perfect stillness.

Occasionally, however, even with these precautions, the removal of a foreign body from the ear is extremely difficult. This is especially so when it has passed beyond the part where the floor of the bony canal dips downwards, as then it at once slips to the further end of the meatus and is not easily laid hold of. If the object is small, and lying loose in this situation, it will often come out by simply syringing. If it has rugged edges, some point of it may be seized with small rectangular forceps; sometimes a loop of wire can be passed beyond it, and so it may be withdrawn. I have removed cherry-stones, pieces of slate-pencil, and other objects, that will roll, but are grasped with difficulty, by the help of a small steel hook; and when a foreign body has been lying in close contact with the membrane, have resorted to a plan some time since suggested by M. Löwenberg, of Paris, and to which reference was made in a former communication to THE LANCET in 1872. "The end of a rod is dipped into melted glue; the point thus armed is held in contact with the foreign body until the glue has hardened (about twenty minutes suffices for this); the rod is then withdrawn, bringing away with it the foreign body." In short, after a good view has been taken of the object to be removed, some one of many modes of procedure will usually suggest itself as the most appropriate in the case under notice; and if one fails, another must be tried. It should also be remembered that no harm will happen by waiting, for, often enough as the ear has been injured by attempts at help, if not interfered with, most things that find their way into the auditory canal (lined throughout as it is with skin) are of themselves as harmless as if held in the hand. Exceptions to this are very rare. Amongst them I may here refer to a case which I reported in the "Transactions of the Clinical Society," in which some plaster of Paris in a semi-fluid state was accidentally poured into an ear, and, rapidly becoming hardened, was only removed after a great deal of anxious trouble; and to another curious instance of the same class of accident, in which, during the past year, I removed, on three different occasions, a piece of a needle. Each piece was deeply imbedded beneath the skin of the meatus, rather more than half way down the passage, and when taken away the three pieces made up the entire needle. The patient, a young lady, had complained for a long time of great pain in the ear, and on examination a very small piece of the needle could just be detected appearing through the skin; this was seized with forceps and withdrawn. The other two pieces were taken out in like manner some days later. No history whatever to account for the presence of the needle could be obtained. From the position of the pieces they could not have been put in by the patient, and indeed there were no grounds for suspecting this.

The mental distress which persons often exhibit from the idea of having something in the ear is familiar enough to us all; and, especially with women, it is not always easy to convince them of their mistake after an examination of the meatus has shown their fears to be groundless. Sometimes whilst picking the ear with a pin they prick themselves, and, dropping the pin, believe it to have been left in the ear. No doubt the energetic endeavours which are made to extract the pin are not unfrequently urged upon the operator, whose ignorance of the whereabouts of the pin is no bar to his enterprise. Within two weeks of writing this I had occasion to examine the ear of a young woman supposed to have a pin in her ear, whose tympanic membrane had been lacerated in the course of a prolonged attempt (which it was proposed to repeat that day) to extract it. As might be expected, there was no pin in the ear. When a foreign body is found impacted in the meatus, it has become so in consequence of considerable violence being used, either at the time it was placed in the ear or subsequently, and no attempt should be made to remove it until all the irritation thereby caused shall have subsided. When it is added, that so lately as during last year a case was recorded in which a child died from meningitis induced by violent measures which were used to extract a stone from the ear, enough will have been said to show the urgent necessity of warning students of the injury they may do, in regard to these cases, unless they proceed with such caution as common sense would seem to dictate, but which does not appear to have received such general attention as is desirable.

Savile-row.

CASE OF

ACUTE CONGESTION AND INFLAMMATION OF THE LIVER;

RAPID INCREASE OF SIZE; EMPLOYMENT OF ASPIRATOR, FOLLOWED BY CONSIDERABLE AND PROMPT RETRACTION OF THE LIVER.

BY HENRY BLANC, M.D., M.R.C.P.,
SURGEON-MAJOR H.M. INDIAN ARMY, SUPERINTENDENT OF THE YERROWDA CENTRAL GAOL.

AGA KYENK-KHAY, a Burmese life convict, aged forty-eight, blind, and seven years in gaol, was admitted into hospital on the 19th of June last with intermittent fever. On account of his blindness this man did no work. He was soft and flabby; but, apart from previous slight attacks of intermittent fever, he had generally enjoyed good health. His present attack was a mild one. On the 22nd of June he complained of pain in the right hypochondrium. A perceptible hard swelling was found to exist in this region, extending laterally and upwards towards the epigastrium and downwards towards the umbilicus. On percussion, dulness was found to begin *anteriorly* a little to the right of the ensiform cartilage, extending downwards in a straight line for about four inches; *laterally* the dulness could be followed some seven inches along the margin of the false ribs, and extending *vertically* from the upper margin of the tenth rib to four inches below it. The swelling occupied the space included between these lines. Deep pressure provoked considerable pain; and percussion, however gently made, was very painful. Measurement across the base of the thorax, keeping over the tenth rib, gave thirty-one inches; and two inches and a half below the false rib and over the most prominent part of the swelling it gave thirty-two inches. Skin cool; temperature under the tongue 96 2°. Pulse small, without resistance, and infrequent. Heart's action very weak; beat of apex not visible nor felt. No cough. No abnormal sound in chest. Breathing weak; respiration 22. He does not sleep at night on account of the pain in the side. Bowels costive; tongue dryish; appetite bad. Urine scanty, light-brown, and slightly acid; density 1025; slight cloudy deposit by heat and nitric acid; no bile pigment. Ordered a mild saline and carminative aperient; an ounce of brandy, the yelk of two eggs, and half an ounce of white sugar, in a pint of milk—half to be taken morning and evening; a diet of rice and mutton broth; also fomentations to the side, followed by the application of collodion.

24th.—Improvement in general condition. The pulse is better, more resistant; bowels freely open; appetite improved; tongue moist. Pulse 90; respiration 34; temperature in armpit 97·2°, in rectum 10°. The breathing is somewhat frequent; no cough; no dulness on percussion; no abnormal sound. He complains of considerable pain in the hepatic region; the swelling has increased and is more globular; no fluctuation. Measurement: Along tenth rib, 34 inches; two inches and a half below false ribs, 34 inches.

Dr. Cruickshank and Dr. Simpson, who kindly saw the patient in consultation, were with me of opinion that the swelling was due either to the presence of a deep abscess or to considerable congestion proceeding to inflammatory action. The man's general condition was not favourable. His habit of body, caused by his forced sedentary life, would alone have made the prognosis doubtful; the heart was evidently very seriously affected, and had almost lost its propulsive power. Relying on the favourable report given by Professor Maclean, of Netley, on aspiratory punctures of the liver, we agreed to operate, believing that, even should we fail to give relief, still we possibly could do our patient no harm. With No. 2 trocar of Dr. Potain's aspirator, a puncture was accordingly made in the most prominent part of the swelling—i. e., three finger-breadths and a half below the right false ribs, and four finger-breadths from the mesial line. About an ounce of black blood was withdrawn, and, under the microscope, we observed mixed with it a few pus-globules.

25th.—Morning: Passed a good night; pulse fair; less pain on percussion. Temperature in rectum 102°; pulse 92; respiration 26; urine slightly albuminous.

26th. — Evening: Temperature, rectal, 100; pulse 90; respiration 26. Continue stimulant draught. He had passed a good day.

29th.—Did not sleep last night; complains of much pain in hepatic region. Pulse firm, more resistant, 90; rectal temperature 100°, in axilla 98 . Treatment: Application of eight small caustic issues to the side; mild saline aperient, with carminative in the morning; continue brandy-and-eggs; two grains of opium at night.

July 1st.—For the last two days he has felt less pain and sleeps well; the appetite is pretty fair; œdema is making its appearance in different parts of the body, specially in the left leg and arm. Continue brandy, eggs, and same diet.

2nd. — Liver decreasing rapidly in size; measurement along tenth rib 29 in.; two inches and a half below, 30 in.; general anasarca more marked. Pulse very small, infrequent, regular; urine scanty, high-coloured, albuminous; temperature in rectum 100°, in axilla 97°. Continue eggs, brandy, and a stimulant draught to be given in small doses frequently. Diet: sago, conjee, and milk.

11th. — Passed a restless night; anasarca increasing; serous effusion in pleural and abdominal cavities. Pulse filiform; temperature in axilla 97°, in rectum 100°. Intellect clear. Gradually sank, and died at 3.30 P.M.

Autopsy, fifteen hours after death (assisted by Dr. Simpson, civil surgeon, Poona).—Head not opened.—Chest: The walls of the thorax œdematous. On opening the cavity of the chest the lungs were found small, somewhat retracted, healthy, with but slight congestion of inferior margin; about half a pint of fluid serum, with fat-globules swimming over it, existed on both sides; old adhesions were found existing between the lungs and the walls of the chest, some so very strong and resistant that they had to be divided with the knife; weight of lungs, two pounds and a half. The pericardium was adhering to the heart intimately, and in some parts was dense, hard, almost cartilaginous. The muscles of the heart had in many places entirely disappeared through fatty degeneration; they were pale everywhere, and presented the appearance of a pathological specimen that had remained for years immersed in spirit. Valve dotted with fat. Weight of heart, with pericardium, seven ounces.—Abdomen: The stomach and bowels were much inflated; the peritoneum was slightly injected in places, more so along the greater curve of the stomach; no effused lymph, but a certain quantity of serous transparent fluid escaped when the abdominal walls were open. The liver was almost entirely hidden under the false rib; the left lobe was small and flat, the right was flattened, presenting a thin border extending irregularly below the false ribs for about an inch. The liver was of bright-yellow colour, hard, and leaving a fatty layer on the knife; it seemed *ex sangue;* the external covering was in places thickened, and here and there it had contracted intimate adhesions with the diaphragm. Through the cellular and intervening tissues the puncture could not be traced; on the liver itself a small punctured cicatrix was found, corresponding in a perpendicular line with the external cicatrix, but several inches higher up, and just on the margin of the false rib. Neither here nor anywhere else could any traces of recent inflammation be found. Weight of liver three pounds and a half. The gall-bladder was elongated, hard, and contained about an ounce of very thick, dark bile, looking very much like pitch in colour and consistency. The kidneys weighed four ounces; there existed some slight injection of the pyramids; the cortical substance was healthy, except towards the inferior extremity, where hard patches were found surrounded by a fatty unvascular tissue. The muscles of the abdomen were pale, flabby, streaked with fat, and in some places the muscular tissue itself had undergone fatty degeneration.

Remarks.—The case is interesting, as showing how very harmless puncture of the liver really is, and it exhibits in a remarkable manner the influence of local bleeding on a liver gorged with blood. Although the symptoms indicated in some degree the existence of an abscess, none was found, but, from the presence of pus-globules in the blood withdrawn, it is evident that before long such a result would have occurred. *The liver was punctured three and a half fingers' breadth—say two inches—below the false ribs,* and at the post-mortem examination the liver was found so much reduced in size that its flattened edge hardly extended half an inch below the ribs; *the cicatrix of the puncture was seen hidden by the walls of the thorax,* whilst the symptoms observed during life, as well as what the autopsy revealed, proves clearly how rapidly the congested and inflamed liver recovered its normal condition after the puncture was made. The amount of blood abstracted was small—not more than an ounce. It seems as if the withdrawal of this small quantity of blood were sufficient to assist the overloaded hepatic vessels, and gave the required impetus to the languid circulation of that organ. Death was due to anasarca, the result of extensive fatty degeneration of the heart and muscular tissues generally, and it was in no respect hastened by the operation, which may have had, even in this fatal case, rather a beneficial effect than otherwise.

REPORT OF A SUCCESSFUL CASE OF THE

APPLICATION OF ESMARCH'S BLOODLESS SYSTEM TO THE TREATMENT OF ANEURISM.

By Staff-Surgeon WALTER REID, M.D., R.N.,
ROYAL NAVAL HOSPITAL, PLYMOUTH.

(*Communicated by the* Director-General of the Medical Department of the Navy.)

J. F——, aged thirty-seven, chief boatswain's mate, was received from H.M.S. *Arab* on August 10th, with a left popliteal aneurism, of the sacculated variety. The tumour had attained a considerable size with strong pulsation. It was caused by a strain incurred three weeks previously while lifting sails.

Strict rest, with farinaceous diet, were first enjoined, and on the 19th treatment by genuflexion was commenced. On the 23rd this was abandoned, owing to the severe pain and œdema of the leg which it caused. On the 26th two Carte's compressors were applied, one to the main trunk at the pelvic brim, the other at the apex of Scarpa's space. After four hours' continuous compression, pulsation in the aneurism ceased, but shortly afterwards returned. Numerous attempts have since been made by various forms of compression to arrive at a cure, but without success. Pulsation continued, and the swelling did not sensibly diminish. The aneurism was apparently being supplied to a certain extent by the collateral circulation.

On the 10th of September, having performed a protracted operation for necrosis of the femur in another patient, during which the limb was kept bloodless for an hour and ten minutes without producing any subsequent injury or inconvenience to the circulation, it occurred to me that Esmarch's system was well worthy of trial in the case of aneurism, as more likely than any other plan, to produce complete stagnation of the contents of the sac, and so lead to their coagulation.

Accordingly I removed the compressing apparatus which was in use that day, and left the patient alone till the morrow, when, at 10.20 A.M., I bandaged the limb with the elastic roller, from the toes upwards to the junction of the middle with the lower third of the thigh. It was applied lightly over the aneurism, so as not to compress it. The elastic tubing was then wound round the limb over the highest turn of the bandage, which was now removed. The entire circulation below the tubing was found to be arrested. The limb had assumed a death-like pallor, and gradually lost temperature. The aneurism was of its usual size, and pulseless.

After fifty minutes, the patient complaining of severe pain above the seat of constriction, a Carte's compressor was adjusted to the main trunk at the pelvic brim, and the elastic tubing removed. On raising this compressor a few minutes afterwards, I could detect no pulsation in the aneurism; several small vessels were beating strongly round the joint, and the collateral circulation appeared to be established. The compressor was readjusted and left in charge of the patient, who had already been well accustomed to its use. He was ordered to apply the compression lightly and in an intermittent manner, so as not to distress himself. He continued doing this more or less until the evening of the following day, when the apparatus was removed. The tumour had been frequently examined by myself and others, and was always found to be pulseless and sensibly diminishing in bulk.

Sept. 15th.—There has been no pulsation, and the swelling is still getting smaller, so that I regard the aneurism as practically cured. There has been no constitutional disturbance, and the only complaint which I have been able to extract from the patient is a feeling of numbness in the three outer toes, with occasional darting pains up the outer side of the leg. The femoral artery can be felt beating as far as the seat of constriction (where the tubing had been placed), but not beyond. There are several small arteries pulsating round the joint, one particularly to the inner side of the patella. The numbness and pains complained of are to-day nearly gone.

Remarks.—The simplicity and apparent safety of this mode of treating aneurisms, as well as the rapid success which followed its application in the case which I have recorded, will doubtless commend it to many as at least worthy of trial.

I have been particular in giving the details of treatment, as any one of them may have been essential to success. The explanation appears to be—the coagulation of blood in the sac, consequent upon its complete stagnation. The aneurism itself probably remained full, but the entire circulation in the parts was arrested, and it is possible that the loss of temperature and that particular condition of the tissues closely allied to death, may have had some effect in the formation of the coagulum. How long it may be necessary to keep the limb bloodless in order to produce this result is a question which must be decided by future practice.

My reason for compressing the main trunk for some time afterwards was that the force of the blood-current might have broken down and washed away the newly-formed clot before it had time to become tough and solid, and the sac to contract over it.

The experience of surgeons will no doubt suggest improvements in this plan of treating this disease. It may be even necessary in certain cases to inject fluids into the sac to promote coagulation while the limb is kept bloodless. This, however, is a mere suggestion, and I must content myself for the present with indicating and illustrating by a practical example what, so far as I know, is a new treatment of aneurism, as well as an instance of the great service which Esmarch's system seems destined to render to surgery.

HOSPITAL PRACTICE,
BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum, tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Prooemium.

MIDDLESEX HOSPITAL.

MELANOTIC SARCOMA OF FEMORAL GLANDS, SECONDARY TO TUMOUR OVER THE HEEL; SARCOMATA IN SPLEEN AND ILIAC GLANDS.

(Under the care of Mr. DE MORGAN.)

THE most remarkable circumstance in the following case was the presence of all the symptoms of brain tumour—headache, vomiting, and double neuro-retinitis, exceedingly well marked and persisting to the end. In no case could the presence of a brain tumour have been diagnosed with more confidence than in this one, and yet at the autopsy no sign whatever of any coarse brain disease was found.

The clinical notes are from the pen of Dr. Lyell, surgical registrar.

E. W——, aged thirty-six, admitted on Jan. 30th, 1875, with a swelling in the right groin, preventing locomotion. Her statement was to the effect that, for eighteen months before admission, she had noticed the steady growth of an almost painless tumour below the right groin, which gave her a minimum of discomfort, till, by pressure on the veins of the limb, causing œdema, and by its size, it prevented her getting about; that, during Easter of 1874, at a metropolitan hospital, a "lump," like a black wart, of the size of a half-crown, was excised from the calf of the right leg; and that this existed some months before that in the groin, although the latter was evident at the date of the operation. Her former health had been fairly good, and there was no hereditary history of any import.

Visual examination reveals a large protuberant mass situated immediately below the fold of the right groin (which is deepened in contrast), occupying the entire anterior aspect of the upper fourth of the right thigh, extending inwards to the edge of the adductors and outwards to the anterior superior iliac spine. It is hard, nodulated, and of equal consistence. She can bear free manipulation of the tumour, but complains of shooting pains in the tumour itself and down the same leg. The tumour is freely movable on the tissues beneath, and the skin surmounting it is natural in appearance, non-adherent, and slightly œdematous. The rest of the limb is markedly œdematous. Above Poupart's ligament, and apparently detached from the mass below, dipping deeply into the brim of the pelvis, is a similar hard enlargement, the upper border of which is circumscribed and rounded, whilst the lower and deeper cannot be localised. Just below the swelling of the right calf is the cicatrix of the operation, and below its site a pea-like melanotic cutaneous nodule.

Feb. 16th.—Since admission, the prevailing and most prominent symptoms have been obstinate vomiting and headache, defying the remedies applied. With the exception of occasional remissions of varying intervals, she has been persistently sick after her food. The remission may last for twenty-four to forty-eight hours. Describes the headache as a "dizziness" and "numbness" creeping up the right side of the head. Tumour remains unchanged. Pulse very feeble and quick. Is evidently losing flesh, and facial expression is more pinched and careworn.

26th.—Constant headache, generally aching throughout, and very sick; her food creates nausea, but occasionally the food is regurgitated without nausea; aching and heaviness in the eyes; reading causes pain and a mist before them; pupils dilated, sluggish, equal. Pulse 78, feeble; bowels rather constipated; urine 1022, acid, no albumen.—Examination of fundus oculi: Well-marked neuro-retinitis in and around both optic discs, which are obscured and veiled by exudation; veins swollen and tortuous, and the vessels near the discs obscured and lost to view in parts of their course; a few recent hæmorrhages in retina.

March 12th.—Passed a bad night; a good deal of sickness in the night; complains of shooting pain along the spinal region; thirst; pulse 90, weak, full and variable; bowels confined; temperature 98°; pupils dilated; mouth drawn to left; left lid closes more firmly than the right; when lids are compressed, the wrinkles on the left side are more marked, but right brow is unfurrowed; pale and anxious.

15th.—Paralysis more marked; complains of pain in head running down the back; pulse 88 and irregular; has singing in the head. Morphia injection twice a day.

19th.—Morphia relieves pain, but not vomiting; her chief complaint is now the pain in back, of an aching and shooting nature, and almost unbearable; the facial palsy, if anything, more pronounced; no palsy elsewhere; neuro-retinitis remains *in statu quo*; has obstinate constipation; bowels opened by croton oil injection.

29th.—Slight internal strabismus of right eye; no vomiting for four days.

April 2nd.—Facial palsy is less marked; can close the right eye firmly, can close the right lid firmly, and the right angle of the mouth moves as freely as the left; the right globe is slightly turned in, and looks a little prominent; for last fortnight has had numbness in both hands, stretching up the arms; this also is less marked.

5th.—Facial palsy has disappeared; hands still benumbed; loss of command over bladder; catheter used; constipation continues.

10th.—Has some command over bladder.

22nd.—Emaciating considerably; very little nourishment retained; tumour in thigh much increased, elastic and bossy to the touch; skin stretched, marbled with dilated veins, and of a purplish colour; gives her no pain.

May 6th.—Continues to lose ground; still no command over bladder; vomiting continues, and headache not ameliorated; very rapid increase of growth.

21st.—Hæmorrhage from tumour stopped by styptics.

23rd.—Again hæmorrhage, about four ounces. The measurements of the tumour are now twelve inches and a half by thirteen inches and a half. Perchloride of iron and ice to tumour.

28th.—Gradually sank after a fresh hæmorrhage.

Abstract of post-mortem examination made thirty-one hours after death. (By Dr. Coupland.)—The upper part of right thigh, from Poupart's ligament to about junction of upper and middle thirds, is occupied by a large dark-coloured tumour, which is in great part broken down to a softened pulp, the removal of which leaves a large excavation with ragged sloughing walls. The depth of the tumour does not extend beyond the fascia lata of the thigh. At the back of the lower part of the leg, about two inches above os calcis, is a linear cicatrix, close to which is seated in the skin a small, low, black nodule, of the size of a pea, and of the consistence of horn. A vertical section shows the nodule to arise from the papillary layer of the corium. Heart and lungs fairly healthy. Liver soft and flabby. Spleen large, pale, soft, almost diffluent; the lower extremity of the organ occupied by two white rounded masses; one of them softened in the centre into a small cavity containing blood; no melanosis. In the omentum were several nodules the size of haricot beans, of soft consistency, and yielding an abundant milky juice. In the right iliac fossa was a tumour the size of two fists, surrounded by large masses or altered glands. The tumour apparently arose from the inguinal and iliac glands. It was of whitish-grey colour, and excessively soft, while many of the enlarged glands, which showed similar appearances, were riddled with little cavities due to post-mortem emphysema. Kidneys soft and flabby. Brain was carefully examined, and no tumour could be found of any sort.

GUY'S HOSPITAL.

CANCER OF RECTUM; COLOTOMY; DEATH NINE MONTHS SUBSEQUENTLY.

(Under the care of Mr. Bryant.)

The following notes were taken by Mr. W. Brown.

G. S——, a paper packer, aged fifty-six, was admitted into Job ward on April 14th, 1873. He had in October, 1872, been admitted a patient, having a large indurated and ear-shaped growth, about two inches long, one inch deep, and about half an inch thick, on the left side of his anus, almost closing the anal orifice; there was also a large fistulous opening at the base of growth communicating with the bowel. Chloroform was given, and on Oct. 25th the growth was removed by galvanic cautery. No bleeding occurred, and the patient left the hospital on Nov. 13th, as nothing more just then was done.

After leaving he remained at home for a week, and then went to work. His motions gradually became smaller, and at last he was obliged to take aperient medicine. He then began to get weak, and was unable to sit down.

When admitted it was with difficulty that the finger could be introduced, so blocked up was the rectum with cancer substance, which bled as soon as it was touched. It was then decided to perform colotomy.

April 16th.—The man was put under the influence of chloroform, and a slightly oblique incision was made between the last rib and the crest of the ilium from above, and in front downwards and backwards. Some difficulty was experienced in getting the bowel up into the wound. The wound was slightly enlarged forwards, then the gut was secured, a needle was passed through the skin and gut in two places, and the bowel cut between them, and the sutures pulled out of incision, divided and ligatured on each side. Another suture was then put in the bowel and skin at the posterior part, and the incision brought together by superficial stitches. The finger was passed down the bowel, and no carcinoma was found as far as the finger could reach. He complained of great pain when he coughed, but he felt better the following morning. Temperature 102·1°; pulse 102; respiration 25.

17th.—The pain still continued, and his abdomen was distended and tympanitic.

18th.—He was a little better, and the following day passed a small motion through the artificial anus.

21st.—The artificial anus did not look quite so well; there was more discharge, but not more pain. Temperature 98·5°.

22nd.—The ligatures came away to-day, the discharge still being great. Temperature normal.

28th.—The bowels had been opened, good-shaped solid motions being passed. He complained of pain in the rectum, but opium lotion was applied, and he found great relief.

He was able to get up a little on May 12th, but felt very much fatigued, and the following morning there was a good deal of hæmorrhage from the rectum, which was subsequently plugged, but the patient looked very blanched and felt weak.

May 19th.—The plug was removed, but bleeding recommenced, so that wool saturated with perchloride of iron was again applied.

23rd.—There was a large ulcerated surface round anus, extending forward to perineum and backwards to coccyx.

June 26th.—The patient had since last report felt very weak and low. His appetite was very small, and he slept but lightly.

July 17th.—The man continued very weak. He was passing urine in great quantities through the wound in his anus.

22nd.—Yellow clay was applied to the sore in the anus. He passed his fæces generally twice a day. The clay was continued till the 31st, when it was removed, as it appeared to cause irritation.

August 11th.—The man stated that he was always very wet. It was not known if any urine came by the bowel. He passed some by the urethra, clear in colour.

September 2nd.—He passed urine both by the rectum and urethra, and by the former blood, when he attempted to sit up.

13th.—The cancer was increasing fast. It occupied all the space between the nates. Pulse 90; temperature 97·8°; respiration 24.

October 6th.—He felt no weaker, but when he got up he could hardly stand.

9th.—The cancer had reached the bladder, so that all his water, except about a pint in the day which passes through the penis, is voided per rectum, through the cancerous growth. On passing the finger into the artificial anus, some thickening was felt outside the bowel.

November 3rd.—There was some diarrhœa in the night, which lowered him very much, making the artificial anus tender, and this was treated with zinc ointment. He took compound ipecacuanha powder, and the diarrhœa lessened.

December 3rd.—He complained of his tongue and throat feeling sore.

9th.—He did not feel so well, his bowels being very relaxed; his throat and tongue troubled him also. He continued in this state till February 16th, when he seemed very much weaker and emaciated, and died on the 20th.

The post-mortem examination showed that the lungs were very shrunken and dry; much emphysema of the anterior parts, especially the extreme edges towards the lower parts. The tubes all contained pus, which welled out of them on the cut surfaces of the lung. The tubes also appeared to be distinctly dilated. The peritoneum was healthy; the artificial anus in the left loin was quite firm and healthy. No excessive adhesions or marks of inflammatory action about the serous covering of the bowel in this position; the bowel here was quite healthy. Round the anus there protruded a large lobulated mass of the growth. When the parts had been removed, it was found that this occupied the whole of the lowest six inches of the rectum. It adhered to the adjacent parts, especially posteriorly, so that when it was cut away from the rectum a considerable part of the wall of the bowel was left behind. It formed a most irregular surface, covered with large irregular masses of the growth, which was white on section, but not cerebriform. There was a little pus about the growth near the rami of the pubis, but no abscess of any size. The liver weighed 52 oz. The right lobe was rather coarse and flattened, with some congestion of the hepatic radicles, and perhaps some excess of fat; the left lobe was remarkably atrophied, flaccid, and, on section, dry, and its lobules much smaller than those of the right lobe. This state seemed to extend right up to the falciform ligament. The kidney weighed 8½ oz., was pale, but not apparently diseased. The ureters were healthy, and not involved in the growth. The bladder was quite healthy, its mucous membrane pale; it had no communication with the rectum, nor had the urethra; it contained a thickish bright-yellow fluid, looking exactly like fæcal matter from the small intestine, but without odour; it also gave no reaction of bile-pigment with nitric acid. Examined microscopically, it turned out to be urine full of crystals of uric acid. It must be supposed that the urine believed to have been passed from the rectum was really discharge from the surface of the growth within the bowel. Microscopically, the growth in the rectum was found to be true cancer—large epithelial cells, with great oval nuclei, and bright nucleoli.

BRISTOL ROYAL INFIRMARY.

NEARLY FATAL CASE OF POISONING BY A KNOWN DOSE OF CARBOLIC ACID; VENOUS INJECTION OF AMMONIA; RECOVERY.

For the notes of the following interesting case we are indebted to J. E. Shaw, M.B., house-surgeon, under whose care the patient really was.

Charlotte C——, aged thirty-seven, a debilitated anæmic woman, confined six weeks previously, was admitted on the 5th June, 1875, for abscess superficial to the right hip-joint, which came on a fortnight after parturition.

It being intended to open the abscess under an antiseptic veil, a solution of carbolic acid in linseed oil (1 to 10) was ordered for that purpose; and of this mixture, on June 7th, the woman, on her own responsibility and unknown to the nurse in charge of the ward, took a measured fluid ounce, not having partaken of any solid food for several hours. Twelve minutes or more elapsed before the woman's condition arrested the attention of the nurse, who, finding upon inquiry what had occurred, hastily summoned the house-surgeon to the patient. When first seen the woman was sufficiently conscious to reply when spoken to sharply; the skin was moist, the face dusky, the pulse weak, and the pupils slightly dilated. The rapidity with which the toxic effects of the carbolic acid were being developed clearly showing that it was useless to temporise with emetics, the stomach-pump was immediately obtained and applied, the stomach being continuously washed out with tepid water for about twenty minutes, until the ejected matter was perfectly free from oily particles floating on the surface and possessed odour neither of oil nor acid. During this time the state of the patient was becoming every moment more alarming. Unconsciousness was rapidly becoming absolute, the dusky tint of the face deepened, the moisture of the skin increased, and the pupils more dilated, while the pulse was rapid, irregular, and scarcely perceptible; the breathing remained regular, although the relaxation of the soft palate rendered it noisy.

In about three-quarters of an hour from the time when first seen, the condition she presented was most singular. Coma was complete, the face perfectly livid, the pupils dilated, the skin secreting perspiration in the most extraordinarily profuse manner, the surface of the body warm, as also were the extremities, with the exception of the hands, the pulse at the wrist imperceptible, and the muscles of the soft palate and tongue so entirely relaxed that it was necessary to keep the latter organ extended with catch-forceps to prevent it from falling back upon the glottis; yet with these precautions the breathing continued regular, though slow, and the reflex sensibility of the conjunctiva was never altogether abolished.

As dissolution now seemed imminent, it was determined to inject ammonia into the veins, and with all possible despatch. Two drops of the strong solution of ammonia diluted with water were gradually injected into a vein of the forearm. In a few seconds the radial pulse became perceptible, and there was slight general improvement, which was, however, but transient, for in a quarter of an hour it was necessary to repeat the injection the same as before, and again with marked benefit. After waiting another fifteen minutes, the injection of ammonia was again administered, after which the pulse remained perceptible, and the patient's condition improved in every respect. Within another half-hour consciousness had returned, and in less than two hours from the time when first seen, she had sufficiently recovered to be left in charge of two students, who had rendered most valuable assistance throughout.

On recovery she was completely ignorant of what had occurred, and did not know that any mistake had been made. She complained of no pain except in the tongue, and experienced no relapse, but remained in partial prostration for some days, and suffered from an attack of gastric catarrh, which subsided under appropriate treatment.

The urine was not examined.

The case is one of interest, inasmuch as the dose taken (as nearly as possible fifty grains) was accurately known, and the symptoms throughout closely watched. This quantity of carbolic acid would appear to be about the limit which can be taken without a fatal result following; indeed, had the acid been in watery solution, and therefore capable of more rapid absorption, or had the woman been left without treatment, recovery would in all probability not have taken place. The experience of this case demonstrates, moreover, the value of injection of ammonia into the circulation in such cases, where we have no direct antidote, and shows that if life can be maintained for about a couple of hours, one may hope to have obviated the tendency to death.

Mr. H. A. Cæsar, public vaccinator, Western district, Mile-end, has received a grant of £36 19s. from the Local Government Board for efficient vaccination.

THE MEDICAL HISTORY OF THE DUTCH WAR AGAINST ATCHEEN IN 1873.*

In 1870 Holland exchanged with England her West Coast possessions for the North-West point of the island of Sumatra-Atcheen. Both powers were soon involved in war by their new dependencies, the English with the Ashantis, and the Dutch against the Atchinese.

On March 22nd, 1873, the Dutch expedition left Batavia, and sailed into the Atcheen Roads on April 5th. It disembarked on the 8th, and found itself, after several severe engagements, before the town of Atcheen on the 14th; but, being unsuccessful in its efforts to reduce the outlying Craton Fort, was compelled to return to the Coast, and re-embarked on April 28th. Of the sanitary arrangements, surgical performances, and medical occurrences of this "three weeks' campaign," an account follows.

The projected strength of the expedition was:—*Military:* Three European battalions (600 each), 1800; Barrissans (native soldiers), 800; cavalry and artillery, 50; convict labourers, 1000; total, 3650.—*Medical:* Medical officers, 12; apothecaries, 2; army hospital corps, 100.—*Material:* Medicine chests, 8; field bandage boxes, 8; stretchers, 12. Accompanied by soldiers' wives to the number of 8 per company, the total reached 5000. Estimating at the rate of 20 per cent., arrangements were made for 1000 sick, and the sailing ship *Kosmopoliat* was fitted out as a hospital-ship. The materials were stored as far as possible so as to form a succession of ambulances, in order that they might be served out more quickly as such on arrival. Besides the regulation stretchers, a number were prepared after the fashion of the Chinese tandus (dandies); each consisted of a piece of sail-cloth 6 ft. 6 in. long, and nearly square, attached to a thin stick at the head and foot, and slung from a thick bamboo about 15 ft. in length by strings from either end, which were prevented from slipping towards the centre. At each extremity of the main pole was hung a joint of hollow bamboo as a water-bottle, and a mat 4 ft. 6 in. long was provided as a cover against sun and rain. To support the dandy while the bearers rested, sticks, hollowed at one end, and shod with spikes at the other, were furnished.

To fit the *Kosmopoliat* for hospital purposes, the following alterations were made:—Port holes were formed, large openings were cut in the deck for the introduction of wind-sails, and existing partitions between decks were removed, only such divisions being allowed as were required for definite purposes; the middle plank was taken out of the roof of the middle deck and trellis-work substituted. A surgery and operation-room were erected on deck. Latrines for the natives were built overboard, those already existing on the deck sufficed for the Europeans, and close stools were carried for the sick. Iron bedsteads were clamped to the floor, and were placed at such distances that a close stool could be introduced between them; beds and seats were also secured on the deck.

A code of instructions was drawn up by the surgeon-in-chief for the guidance of those under him, in which all due importance is given to the necessity for hygienic care; the disinfection and ventilation of rooms used for hospital purposes are insisted on, with a warning against overcrowding, and advice that the men's stretchers should, whenever possible, be raised one foot above the ground, unless where the house is built on piles. A caution is added against placing hospital huts to leeward of a swamp. All slaughter-house offal is directed to be thrown into running water below the encampments, or to be buried. The greatest stress is laid upon attention to the drinking-water, the examination of which is never to be omitted, and where percolation through the regulation filter-stones is not deemed sufficient, a layer of powdered charcoal is to be added, and the water, if especially cloudy, to be previously treated with solution of sesquichloride of iron and soda. Carbolic acid is to be invariably mixed with the water for washing wounds, and this is to be applied with charpie only, as sponges are considered dangerous. Charpie once used to be buried or burned.

On the subject of operations the following opinion is offered:—According to the experience of the last war, conservative treatment in wounds and fractures of the upper extremity affords every prospect of success; so are primary amputations and disarticulations only in the most pressing cases to be undertaken. This rule holds good also for the lower extremity, since removal of it above the knee, whether primary or secondary, for the most part results in death. The application of permanent bandages should be made as early as possible, and will be an indispensable preparation for later resection. Each medical officer is required to send in a medico-sanitary report of his duties during the campaign, and by this he will be in a great measure judged.

The distribution of medical officers for the voyage from Batavia to Atcheen was as nearly as possible that which would be the allotment on landing. Two medical officers and two apothecaries went in the hospital-ship, the remainder were apportioned to different corps. To each medical officer were assigned two non-commissioned officers and eight men of the Army Hospital Corps, one medicine box, one bandage case, eight "tandus" complete, and a water-flask.

On March 22nd the flotilla left Batavia for Penang, which was 250 miles distant, signals having been arranged so that any case of infectious disease could be at once reported and removed to the hospital-ship. None such, however, occurred, notwithstanding the state of overcrowding which existed.

A sanitary inspection of the fleet was made on arrival at Penang, and showed the condition of the troops to be remarkably healthy; only fifteen sick were transferred to the hospital-ship. Yet it was regarded by the surgeon-in-chief as fortunate that little delay was made here, since at evening with the land-wind an intense swamp-air was carried over the harbour, the influence of which made itself felt on many of the ships during the subsequent voyage in the form of fever with gastric derangement.

On the morning of the 2nd of April the fleet left Penang, and dropped anchor in the harbour of Atcheen at midday on the 5th. Here all sick were at once removed to the hospital-ship, and numbered sixty-two, of whom thirteen were fever cases and three bowel complaints; of these, one fever case and one bowel case subsequently died.

That throughout a voyage of fourteen days' duration in the tropics, notwithstanding an almost reckless condition of overcrowding, only seventy-seven cases of illness should have occurred out of a strength of 4019, exclusive of women and servants, seems a most undeserved piece of good fortune, and was attributed by the surgeon-in-chief "to the good quality of the drinking-water obtained from Batavia *above all things*," and, secondarily, to the fair weather experienced.

The actual composition of the expedition was—officers, 170; Europeans, 1064; natives, 2185; convicts, 600. These were embarked at the rate of 700 per steamer, and, while in the English Abyssinian expedition transport was provided at the rate of 3½ tons per head (2·7 tons being the average laid down in Dr. Parkes's work on Hygiene), the Dutch expedition estimated for only 1½ tons to each individual. Again, whereas in the former every European soldier was allotted a superficial area of 10½ square feet, and every native 9 square feet, yet in the latter the superficial area did not amount in all to 6 square feet a man. Against such a state of things the strongest remonstrances were entered by the sanitary authorities, but remained unheeded, so that, emboldened by this escape, another much stronger force, which left Batavia eight months later, were still more closely penned, but with sadly fatal results.

On arrival at Atcheen one of the ships was told off for the reception of slight cases of illness, and 61 beds were thus vacated in the hospital-ship, which contained but 100 altogether.

On the 6th, the Commander-in-Chief, Major-General Köhler, made a reconnaisance, in which 1 man was killed, and 3 wounded.

On the 7th, medical dispositions were made:—To each battalion were assigned two surgeons, who also provided for the attached cavalry, artillery, and convict labourers. At the disposal of each surgeon were ten men of the Army Hospital Corps, and twenty labourers, for the purpose of forming an ambulance. Each battalion had thus two ambulances. The remaining two surgeons and one apothecary were left on board the hospital-ship, and the second apothecary was detailed to act as analyst to test the various wells for poison and purity.

---

* Epitomised from the account by W. Roth, Generalarzt des 12 Armee Corps.

On the 8th the disembarkation was completed, with the exception of some artillery and cavalry; but, notwithstanding a galling fire from the landing troops, covered by a cannonade from the fleet, the Atchinese withstood their assailants breast to breast, crossing sabres with bayonets, so that in the capture of the first fort the Dutch lost 15 killed and 58 wounded.

On the 9th the second fort was taken without resistance after a breach had been made by the guns of the fleet.

On the 10th, an expeditionary column, under the commander-in-chief, was organised for an advance on the town of Atcheen, between three and four miles inland. Those remaining at the sea-shore transferred their camp into one of the forts, in the neighbourhood of which good drinking-water, with scarcely a trace of organic matter, and capable of being used without purification, was found. The excellent quality of this water, discovered on a little strip of land between the sea in front and a large swamp behind, was a subject of great surprise, and could only be explained by supposing that the drainage of the distant hills filtered thither through a stratum of sand beneath the lagune.

The troops of the advancing column had to cross a bridge under an Indian forenoon heat, and attack a mosque standing in front of the Craton fort, which defended Atcheen. The assault was unsuccessful, and resulted in so many wounded that the four surgeons who had accompanied the troops in the engagement were insufficient, so that of the two, the senior medical officer and a surgeon, left in the rear to establish a bandage-place not under fire, the latter had to go forward, leaving only Dr. Theunissen to make the necessary arrangements. He, having discovered a dry, airy house by a small churchyard, and finding good water within easy distance, laid down fresh rice-straw, and prepared as far as possible for the reception of the wounded.

On this and the following day 71 wounded were passed on from this first dressing-place to the base of operations on the coast, and the hospital-ship being incapable of accommodating so many, only the badly wounded were sent on board, while the remainder were treated in two field-hospitals erected on the shore out of bamboos, matting, blankets, and sailcloth. In the meantime, to make room, 39 of the previous sick and wounded were evacuated by steamer to Padang, a Dutch settlement 120 miles lower down on the coast of this island of Sumatra.

On the 12th another reconnaisance was made against the Craton, which resulted in a bloody but unsuccessful fight, in which 5 were killed and 49 wounded. The improvised dressing-place was evacuated as far as possible, all transportable wounded being sent to the field-hospitals on the coast.

On the 13th there was a slight skirmish, in which 1 man was killed and 12 wounded.

On the 14th an unsuccessful attack was again made against the Craton, but the mosque was taken after two assaults. On the capture of the mosque, orders were given for the advance of the reserves and ambulances from the bandage-place by the churchyard, since the means of carrying the wounded thither were becoming less and less, owing to the desertion of the Coolies from fear. By energetic measures the Coolies were again collected, and the wounded were carried to the mosque, where, under cover from fire, they were laid in the open, shaded by palm-leaves from the sun. On this day the commander-in-chief, Major-General Köhler, was killed by a ball, which passed through the left arm and penetrated the chest. Death was instantaneous. The casualties amounted to 9 killed and 107 wounded; of the latter, as many as possible were carried to the sea-shore ambulance.

To convey an idea of the determined bravery with which the Atchinese fought on this occasion, the following description is given:—"By our advance the excitement of the Atchinese was so far heightened that they no longer avoided an engagement in the open, but appeared in dense masses, each with a firelock, a lance, and two sabres. They ran towards us with wild war cries, fired, threw down their pieces, then hurled their spears, and rushed forward with brandishing sabres. The quick fire of the Beaumont rifle occasioned frightful bloodshed among them; the number of victims was countless. When the enemy decided on abandoning the field the ground was so heaped with slain that no empty place could be discovered."

On the 15th of April the 12th Battalion made a reconnaisance, and lost 1 officer and 4 men killed, and 1 officer and 15 men wounded.

On the 16th the attack on the Craton was renewed, but again without success, and with this failure terminated the offensive operations of the expedition. Four surgeons were in action with the troops, and one with the senior medical officer at the bandage-place in the mosque. The loss amounted to 11 killed and 117 wounded. The number of stretchers was insufficient, and others had to be extemporised out of bamboos and covers: 96 wounded were sent back to the sea-shore.

Out of a full strength of 3419 fighting men, the total killed and wounded had now reached 423—a consideration which, combined with the unfavourable state of the weather, made the new commander-in-chief, Van Daalen, hesitate about undertaking further operations, lest he should be ultimately compelled to precipitate the re-embarkation, and leave behind some of his material and the wounded.

On the 17th, the retreat to the shore was carried out in the best order, each ambulance being present with its brigade. The great number of wounded already on board the hospital-ship and in the ambulances made an evacuation indispensable. 89 wounded were accordingly sent by steamer to Padang. Room was thus gained in the hospital-ship, and the most severely injured were brought thither from the shore ambulance, so that the latter could receive fresh sick from the returning troops.

On the arrival of the field column, the little camp required the greatest hygienic care. New wells were dug, and every precaution taken. Of the filter-stones served out little use was made, as, from being new, the water that first came through was unpleasant. In future they should always be cleansed by percolation before being given out.

On April 26th, 70 sick and wounded were evacuated by steamer to Batavia, and on the same day the ambulance on shore was broken up, the 10 remaining sick being transferred to the hospital-ship.

On the 28th the re-embarkation was completed, the hospital-ship then containing 63 sick.

On May 4th the fleet again cast anchor in the harbour of Singapore, and a medical inspection was made, which disclosed a much larger sick list than on the outward voyage, but mostly consisting of slight forms of fever. Twelve were removed to the hospital-ship.

Setting sail on the day following, the fleet arrived at Batavia on the evening of the 9th May.

The number that were found at the time of disembarkation to be unable to march with their battalions, and who were left for transport with the patients from the hospital-ship amounted to 147, composed of 53 wounded and 94 fever cases. Eight of these suffered also from beri-beri.

(To be concluded.)

THE BRITON MEDICAL AND GENERAL LIFE ASSOCIATION.

An extraordinary general meeting of the share and policy holders in this company was held on Tuesday at 429, Strand, Mr. Francis Webb in the chair, for the purpose of receiving the directors' special report and valuation of the position of the Association since 31st December last, and to determine the course to be adopted on the directors' recommendation that a "new series" of members should be established in the form of a new company. The directors' report stated that the valuation to December last, which had been conducted on the same principles as those adopted in the valuation of the affairs of the Association to the end of the year 1872, showed a balance on the valuation of £206,803, making, with £35,420 paid up capital, a balance on the account of £241,503. After considering everything in connexion with the Company's affairs, they had determined to recommend the establishment of a new series of members, as a new company, with separate funds and special capital on which all new policies on the profit scale should be issued, and that the entire existing funds and capital should be specially reserved for the benefit of the present policy holders. They also recommend as a part of the scheme that the expenses of the old company should be comparatively small—for the first two years not more than 8 per cent. on the premiums, for the next five years not more than 6 per cent., and afterwards not more than 5 per cent., including commission to agents. Out of the above-mentioned £241,503, the directors had caused to be reserved £164,424, being the present value of such rate of expenditure. On this scheme they had taken the opinion of four eminent actuaries, Messrs. Bunyon, Adler, Bailey, and Pearson, and on this opinion they felt justified in recommending the adoption of the scheme to the policy and share holders. By this scheme the expenses of the old association would be limited to the smallest possible amount, whilst the new association, forming in itself a large body of recently selected lives, got together at comparatively small expenditure, would have unusual prospects of success. The directors also proposed to strengthen the executive, some of the present directors to devote their attention specially to the management of the funds and the transactions of the old series, and a larger board to be formed for the new series on which the interests of the policy-holders would be fully represented. The special actuarial opinion of Messrs. Bunyon, Adler, Bailey, and Pearson, above referred to, after stating that these gentlemen had examined the accounts and statements for the five years ending 31st December, 1872, deposited with the Board of Trade, and the valuation then made, and that they had tested that valuation, proceeded to say that the accounts for 1873 and 1874, and the results of a valuation to the end of 1874 on the same basis as the former valuation, had also been submitted to them, and they were of opinion therefrom that the events of the last two years had not appreciably affected the Society's financial position, the resulting balance at the end of last year being £206,083 as against £190,688 in 1872. After stating the principle of the new scheme, the opinion of the four actuaries above-named proceeded to say that, "assuming this plan to be carried into effect, the existing business to be preserved, and taking the balance of assets over and above the accrued liabilities to be £659,305, according to the balance-sheet last published, and bearing in mind that the society possesses a large unpaid capital (£142,000) as a further guarantee for the integrity of its assurance contracts, we are of opinion that it will be in a position, with careful and judicious management, to discharge all existing liabilities as they mature. The new company will start with a valuable connexion in complete working order, which has been acquired at an expenditure of much time, labour, and money, and will be free from all existing engagements. Thus circumstanced, and guided by the experience of the past, we think it has good prospects of success." The Chairman detailed at considerable length the advantages of the new scheme, and alluded to the attacks that had been made upon the company by a portion of the press. He, however, insisted that the company was in a sound position. He asked the meeting to pass a resolution authorising the old company to employ the new in the collection of their income from the 31st December, 1875, at the rates stated in the report, including all expenses of offices, clerks, stamps, &c., and that they should relieve the old series from their current business expenses, with the premises and any existing agreements. He then moved, "That the report just read be received and adopted, and circulated." Dr. Richards seconded the motion, which, after having been strongly supported by Mr. Oliver, Dr. Owen (Lord Mayor elect of Dublin), Mr. Chapman (an old shareholder), and Mr. Fox (Dublin), was put to the meeting, and carried unanimously amidst cheers.

THE HUNTERIAN SOCIETY.

THE Council of the Hunterian Society feels that the Society's usefulness would be much increased by the operations being more widely known amongst the members of the profession.

1. The London Institution, Finsbury-circus, in which its meetings are held, now forms the central point on which no less than nine suburban railways converge at only three minutes' walking distance from each.

2. It possesses the most complete accommodation for small as well as very large meetings.

3. Its permanent medical library consists of nearly 4000 volumes, and it has established a circulating one by subscription to Lewis, by which each member can obtain all the latest works on application to the librarian between the hours of 10 A.M. and 4 P.M.

4. It is a Society originally established (fifty-seven years ago) for the purpose of encouraging kindly feeling, friendly discussion, and integrity of purpose amongst its members. These objects it has steadily fulfilled during its course, and has always maintained a sound financial position.

One reason for its being less known than other medical societies is a rule made *in limine* that publication should be avoided lest it should restrict freedom of discussion. Another reason is migration to the West of the men who were at one period of its formation the leading members of the profession. A third reason was difficulty of access to its former place of meeting. This now is changed, and the Council desires to bring the fact as prominently as they legitimately can before the profession.

A CASE OF POISONING BY NEURALINE.

To the Editor of THE LANCET.

SIR,—It may be useful to place on record a case of suicidal poisoning by neuraline, which has just occurred in Marylebone, and in which death appears to have resulted quickly and almost, if not altogether, without a struggle, after swallowing a comparatively large quantity of that extensively advertised preparation of aconite. The deceased, who had previously been in sound health, was a gentleman of good position in Holland, aged thirty-six years, who had lately arrived in this country, and who, in addition to other domestic troubles, had been much overcome by the death of a dearly-loved daughter, which had unexpectedly occurred abroad during the previous week. When the body was first viewed—probably about twelve hours after the poison had been swallowed,—it was found lying in a prone position, inclining towards the left side, with the arms folded and the legs close together and straight. There was extensive and well-marked cadaveric lividity, and the rigor mortis was fully established. On the dressing-table in his room were two small and octagon-shaped bottles, marked "Neuraline," the corks of which had been pushed in, and their fluid contents had apparently been emptied into a tumbler which was found on a chair near the bedside. This tumbler, which smelt strongly of neuraline, had been drained of its contents as soon, probably, as the deceased had undressed and gone to bed. There was a slight smell of neuraline perceptible near the mouth of the deceased, and from a letter, which was found beside the two empty neuraline bottles, it was evident that he had intended to commit suicide.

As no post-mortem examination was allowed by the coroner (Dr. Hardwicke), there was no opportunity of ascertaining the effects of aconite in a concentrated form on the internal organs; nor of verifying previous observations respecting the state of the mucous membrane of the stomach and duodenum in cases of death from this poison. The jury, after some remarks on the absence of a post-mortem examination, returned a verdict of "Death from Suicidal Poisoning by Neuraline whilst in a state of unsound mind."

Neuraline, according to Dr. Harley, is a preparation of tincture of aconite, mixed with chloroform and rose-water; and the death of the Hon. G. R. Vernon, in 1871, was ascribed to the too frequent use of this preparation externally. (*Pharmaceutical Journal*, Jan. 1872, p. 618; cited by Taylor, "Principles and Practice of Medical Jurisprudence," second edition, 1873, vol. i., p. 427.)

I am, Sir, your obedient servant,

WILLIAM SEDGWICK, M.R.C.S.

Park-place, Upper Baker-street, Sept. 22nd, 1875.

⁎⁎⁎ We think that a post-mortem was necessary in this case. Juries in such cases should refuse to return verdicts unless post-mortem examinations are made.—ED. L.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 25, 1875.

AFTER perusing the description and criticism of a huge Act of Parliament, it is somewhat of a relief, if not of a refreshment, to take up a Report (Blue-book though it be) which forms the fourth of a new series submitted by Mr. SIMON to the Local Government Board. The first of these Reports was comparatively brief, and referred chiefly to the circumstances under which these official records had been for a time in abeyance. The second was occupied almost exclusively with filth diseases and their prevention, and contained valuable reports on certain outbreaks of enteric fever by Drs. BUCHANAN, BLAXALL, and BALLARD, and on excrement nuisances by Mr. NETTEN RADCLIFFE. The third Report was devoted to scientific investigations by Drs. BURDON-SANDERSON, KLEIN, CREIGHTON, and THUDICHUM, made with a view to aid the study of pathology and medicine; and was submitted by Mr. SIMON, in his capacity as Medical Officer to the Privy Council. The fourth Report, now before us, contains a valuable digest, by Dr. SEATON (assistant medical officer to the Board), of the vaccination officers' returns; and includes, in fact, a skilled *résumé* of all that has been done officially in this important subject to the end of January in last year. There is also an official communication by Dr. BUCHANAN on infectious diseases in Birmingham and Aston, and on the hospital accommodation of these places; and another by Dr. BALLARD on the sanitary condition of the Upper Sedgeley sanitary district. The Report comprises, moreover, an abstract of the medical inspections made in 1874, with regard to matters of local sanitary administration. We shall hope to notice these communications *seriatim;* for that relating to vaccination directly and practically concerns a vast number of our profession in all quarters of the kingdom, and the various aspects of the hospital accommodation question are no less important to all officers of health. But we desire at the present time to direct attention to the "manner" rather than the "matter" of this Report. In a brief chapter of ten pages, Mr. SIMON describes, in his superlatively terse but exhaustive style, the special objects of the Report, and then proceeds to look ahead, and to indicate to the President of the Local Government Board the best course to steer over an awkward and tortuous route.

In summarising the non-administrative business of the department performed during the past year, special mention is made of Mr. NETTEN RADCLIFFE's unsavoury work (discussed at length in Report No. 2), as to which Mr. SIMON expresses his "grateful sense of the service which Mr. RADCLIFFE rendered in devoting himself for many months with indefatigable patience to details which only the hope of real public usefulness could make attractive." The same inspector now notes for the department all information received as to foreign epidemics from the Foreign, India, and Colonial Offices, and is also compiling a paper on the movements of cholera, which will be shortly forthcoming as a supplementary report, being a continuation of that submitted in 1866 to the Privy Council. Levantine plague is briefly adverted to; and special mention, of course, is made of the International Sanitary Conference held in 1874 at Vienna, at which the department was represented by Dr. SEATON, and of the results of which full particulars were given in THE LANCET of August 22nd of last year.

The ordinary administrative work, as above-named, is set forth in the appendices. "With regard to the prevention of diseases other than small-pox, the Board during 1874 communicated through this department with 56 local authorities, representing 17 rural and 39 urban districts." The context shows that there are, at the present time, 1558 areas of separate sanitary jurisdiction in England and Wales—i. e., 39 metropolitan, 930 urban, and 589 rural districts. Mr. SIMON simply puts these two sets of facts in close juxtaposition (as we have done here), and then says (speaking of the 56 inspections),—"The above communications neither enable me to submit to you any adequate materials for discriminating as to the progress of disease-prevention in the districts of England, nor, I apprehend, can have represented an exertion of the Board influence in favour of sanitary progress in more than a small fraction of the cases where such progress is urgently wanted." This last paragraph, taken with the preceding statistical particulars, needs no comment.

The Medical Officer, in detailing evident signs of sanitary progress, notes the fact that loans contracted under the Sanitary Acts averaged between 1858 and 1864 somewhat less than £330,000 annually; that they more than doubled that amount in the six years from 1864 to 1870; that thence to the end of 1872 (twenty-nine months) the annual average exceeded £884,000; and that in the last two years the respective amounts have been nearly a million and nearly a million and a half of money. As many as ten rural districts in 1873 and forty-four in 1874 applied for and obtained urban powers, and "in many individual cases the reports of the local officers of health give every assurance which could be desired that good sanitary work is advancing." But the unfavourable side of the picture, though indicated only by the Quarterly Returns of the Registrar-General, shows that "preventable death in vast quantities goes on unprevented," and is "conclusive as to the insufficiency of sanitary endeavours in a very large proportion of our local jurisdictions." Two influences commonly predominate in needlessly wasting human life in this country, and these are (1) local conditions of filth and nuisances, and (2) reckless disseminations of contagion. Both show the utter neglect of local authorities to fulfil the definite obligations which the Sanitary Acts impose on them, and their failure to use with adequate skill and vigour the resources which are in their option to employ against the evil.

In emphasising the proportionate unimportance of the proceedings taken by the Board through the Medical Department as to these evils (because of the infinitesimally small number of inspections conducted), Mr. SIMON appeals to the functions of statesmanship rather than of medicine and very properly assumes that "among the many administrative purposes for which central government in this country claims to criticise and influence, and in certain cases control, the action of local authorities, none can be of more national importance than those which relate to the prevention of disease." And (adverting to the statistics above quoted) "how slight, except in regard of small-pox, is the cognisance which the Board hitherto takes, and how far apart are its exertions of skilled influence in regard of those local defaults of disease-prevention which annually cost many thousands of lives."

Mr. SIMON then (assuming that local government should always as far as possible be exempt from central interference) submits that the intervention of the Local Government Board should proceed methodically upon the basis of local death-accounts—i. e., the evidence afforded in such accounts as to the degree in which preventable disease has not been prevented. This intervention might in some cases be attained by correspondence, but (as has been before recorded by the Medical Officer) would be best compassed by skilled inspections on such a scale as practically to represent a central audit of local death-accounts. Such examination of local proceedings as have been hitherto undertaken are made on the basis above suggested. But the quantity of medical inspecting force available to the department for this branch of the service is only about equal to the employment of three inspectors; and this, with 1558 sanitary jurisdictions, and a mortality (excluding small-pox) from preventable causes of at least 120,000 persons annually!

Attention is drawn to the following facts: (1) that the Board are only entitled to receive copies of the reports of their local officers of health a moiety of whose salaries is paid out of the imperial exchequer; (2) that in certain cases local authorities, though provided with admirable officers of health, may, and often do, entirely disregard their advice; (3) that the reports of local officers which come to hand are sometimes so compiled and arranged as to give little or no information to the Central Board. These manifest defects suggest to all familiar with the subject an equally manifest remedy.

Mr. SIMON concludes with a graceful compliment to those local medical officers of health who in many places have filled their posts with credit, and "in a notable number of cases with really eminent ability and success." But this circumstance, as he remarks (having regard to the novel nature of the work), must not obscure the fact that, before such standards can be general in the country, very much work will have to be done and very many difficulties surmounted.

◆

A STRONG argument has been advanced by some members of our profession, whose opinion is entitled to every consideration, in favour of the punishment, in certain cases, of lunatic criminals, and in support—partial, at any rate—of the attitude which our criminal law maintains towards the insane. What that attitude is we need hardly remind our readers. It absolves from punishment those, and only those, who at the time of the commission of their crime were unable to appreciate the wrong character of their action. It includes all others, however distinctly insane, in one condemnation with criminals of sound mind. It ignores the pathological facts of insanity, which show how essentially diseased are all the actions of a mind in any point conspicuously unsound. It ignores the untraceable character of the mental processes in the insane and the obscurity of their delusions; and it applies to their crimes a hard and fast rule which, it is not too much to say, would apply to nine-tenths of the distinctly insane acts of the inmates of our lunatic asylums. To this we need not say the strongest protest has been raised by members of our profession, and to it also a pointed protest has over and over again been given by popular common sense, as expressed by the verdicts of juries and the tone of the lay press.

It has been urged, however, especially in the letters of Dr. KIRKMAN and Dr. MANLEY, that such absolution of the insane from all the consequences of their actions is unjust, and is likely to be attended with grave consequences to society. Many of our criminal lunatics have, it is said, the power of restraining themselves from the commission of their crimes. The distinction between many of their offences and those of the sane is one of degree, not of kind. They may be, and often are, actuated by the same motives, unconnected with delusion, and of no uncontrollable character. It is further urged that one reason why they do not exercise the needful self restraint is the known impunity with which their crimes may be committed. Dr. KIRKMAN, for instance, asserts that "many lunatics are capable of appreciating right from wrong, have a thorough and sound knowledge of the quality of sinful acts, and are morally and physically able to resist their impulses to commit them." He further mentions that BLAMPIED, whose brutal crime will be fresh in the recollection of our readers, on one occasion threatened to murder him (Dr. KIRKMAN), and said, "If I do commit murder, you cannot punish me for it, because it is contrary to the law to punish an insane man."

It may be doubted whether the question is materially altered by these facts. That it is possible for an insane man to commit a crime, in the motives to which no diseased mental processes and moral feelings are at work, must be admitted; but that it occurs, except in extremely rare instances, is very improbable. It is true, also, that every case must be judged by its merits. The application of a fixed line, either of inculpation or exoneration, to the varying phases of mental weakness, must entail frequently unjust results. But although motives of the same class may incite the sane and the insane to a crime, the disproportion in the two cases in the magnitude of the motive is often sufficient to establish an essential distinction. It was so in the case of BLAMPIED, as at the time we pointed out; and we think that the fact mentioned by Dr. KIRKMAN substantiates the truth of our remarks. "Method in madness" is not to be taken as the same phenomenon as "sanity in insanity." And even if unsound minds do sometimes act in their crimes under motives of ordinary character and degree, the extreme rarity of such a circumstance, the impossibility of proving its nature when it does occur, and the liability to a mistake of cruelly unjust results, are sufficient justification for its practical neglect. The mental processes of the insane are beyond all ken. Dr. MAUDSLEY remarks that it would need an insane mind to follow the windings of another. The first principle of social laws and rules is that injustice to the individual shall be as far as possible avoided; and public opinion would at once repudiate the purchase, at the cost of such injustice, of any addition to our social safety and well-being which the frequent punishment of lunatic criminals might possibly secure.

Nor can any greater weight be attached to the argument that justice demands the punishment of the insane offender. Its logical result would be that the punishment would have to be graduated according to the apparent criminality of the offender, to the extent to which his action was the result of motives similar to those which would actuate a healthy mind, and to the extent to which they were capable of self-control. In favour of a sliding scale of such a character some abstract arguments might be urged. But the practical difficulty of its application would probably be an insuperable obstacle to its employment; and it would, moreover, be difficult to justify it on the only sound basis for the punishment of crime. It would probably be found to be of little use in furthering either of the chief ends for which penalties are inflicted—the reformation of the criminal or the preservation of society by deterrent influence. It could be justified only on the principle of retaliation, of punishment as a vindictive measure—a principle which, however deeply it may underlie the practice of jurisprudence and the popular theory of law, must always fail to satisfy a thoughtful sociologist.

◆

THE average Briton is not easily impressed by precept, convinced by argument, or turned by the force of persuasion. He is not even prone to be scared into the discharge of his duty by the parade of dangers attending its neglect. He is obstinate, and he is obtuse. These are the two prominent elements in the English character; and it is scarcely too much to say that, although they are ungainly virtues, to them the nation owes its stability and the State its strength. Obstinate perseverance in the face of difficulties, obtuseness in the apprehension of critical danger or defeat, have been the efficient causes of English success and safety in many an hour of peril. It was these qualities Captain WEBB especially exemplified in his unprecedented achievement.

The extraordinary courage, endurance, and self-control of the great swimmer have been recognised by all classes of thinkers, and no more need be said on this topic, except to point out that the mental effort put forth during the later hours of the performance—sustaining the swimmer through the critical period of exhaustion which supervened after two-thirds of the distance had been traversed and the shore-currents off the coast of France were encountered, and enabling him to put on that gallant spurt which landed him faint but triumphant on the sands of Calais—was probably unique. The retention of animal heat during so long a period of immersion, the muscular energy displayed, and the tact and skill evinced in the maintenance of automatic movements after they had ceased to be automatically performed, are the points of interest with which we are most intimately concerned. It must not be forgotten that it was in an unfavourable climate the task was accomplished. The natives of islands in tropical climes are not unfrequently expert swimmers, and accustomed from their infancy to remain many consecutive hours in the water; but the depression of temperature to which their bodies are exposed by immersion is not nearly so great as that undergone by Captain WEBB. Besides which, the exploits of these islanders are generally performed under the rays of a burning sun, and the heat they lose is quickly replaced by floating a few minutes now and again passively on the surface. In the present instance it must be assumed that the swimmer was entirely dependent on the heat generated within his body by the ordinary process of oxidation, accelerated by the muscular exertion; and, considering the continuous loss entailed by contact with new masses of cold water at each stroke, the maintenance of a vital temperature is most extraordinary. The porpoise-grease with which the surface of the body was lubricated no doubt did much to conserve the caloric, but that was not an unqualified advantage, because, cutaneous exhalation being almost entirely suspended for twenty-two hours, the aerial surface of the lungs must have been surcharged with moisture and the process of oxidation somewhat impaired. It is to be regretted that the conditions did not admit of accurate scientific observation. It would have been most interesting to ascertain precisely the physiological phenomena towards the close of the experiment. As it is, we can only conjecture that an exceptional development of muscular force in the heart and larger bloodvessels, probably extending throughout the arterial system, and giving unusual contractile and propulsive power, may have facilitated the achievement. This consideration should act as a deterrent to adventurers who, with equal courage, may not be so well provided by natural conformation for a similar feat.

The muscular exertion involved in the exploit calls for close attention. Almost all the voluntary muscles are brought into play in the act of swimming; and by the continuance of the act for so long a period, with scarcely any interval of rest, the reserve of strength must have been severely tested. It is no uncommon occurrence to see the muscular powers severely tested. In cases of delirium patients will continue restless and sleepless until wholly exhausted, but it is seldom that precisely the same muscles are in action monotonously during so long a period, and the exertion is generally accompanied by profuse cutaneous perspiration, which in this instance must have been almost absent or greatly retarded. The movements necessary to maintain a body afloat and to propel it through the water are of course performed automatically; but after a period in the performance they must in this case have fallen out of the rhythmical series and called for voluntary control and direct superintendence, just as an overtaxed pedestrian finds it necessary, in common phrase, "to drag his legs after him"; that is, the movements of the lower limbs are no longer performed automatically, in the largest sense of the word: they need to be specifically directed. To some extent this necessity may have been an advantage, in so far as it helped to keep the swimmer on the alert, and did some service in keeping off the tendency to sleep.

Practically, we may learn from Captain WEBB's performance,—(1) That the best training for extreme muscular exertion consists in the establishment and maintenance of a state of sound general health. It does not appear that he subjected himself to any of those artificial and really exhausting processes upon which athletes are apt to lay too great stress, and to which they attach a mistaken value and importance. Any considerable reduction of fat, in the production of what is known as "fineness," would have been an evil not improbably fatal to success, since it would have rendered the deprivation of heat more rapid and extensive. (2) That by judicious management and fortitude it is possible, in an emergency, to perform a prodigy of strength and endurance so that apparently desperate circumstances should not readily inspire the human heart with hopelessness or paralyse exertion. (3—and perhaps this is the most thoroughly practical lesson to be deduced from the extraordinary feat) The most useful and compensative kind of skill is that which enables a man to perform a common act continuously, and under pressure of stern necessity to push the performance to the extreme point of endurance, which, as is proved by this case, lies far beyond the limits of *ordinary* exhaustion. The circumstance that Captain Webb is what may be called a straightforward swimmer was, so far as the mechanical part of his exploit is concerned, the secret of his success. The waste of energy in "fancy swimming" is wanton, and it reacts most injuriously on the art. Plain, straight-ahead swimming with the breast-stroke is the one worthy enterprise. One word in conclusion to the members of our own profession, who enjoy so large a share of personal confidence. It will be doing good service if they miss no opportunity of inculcating the need of expertness in an art too much neglected. The preservation of sound health and the development of the highest physical and mental power are objects worthy of the most constant endeavours, and success will bring the best and most practical recompense as its reward.

Annotations.

"Ne quid nimis."

SPECIAL HOSPITALS.

It has been somewhere remarked that one of the best illustrations of the philanthropical spirit of the age is the number of the medical charitable institutions to be found in every large town, and especially in the metropolis. Although this observation is truthful to some extent, it is not altogether free from a fallacy that usually lies concealed behind the plausible appeals placarded on the walls and hoardings in the public thoroughfares, or published from time to time in the columns of the daily newspapers. We speak only of special hospitals. On every hand there are hospitals for this and hospitals for that, hospitals everywhere, all professing to have for their single aim the alleviation of human suffering and distress gratis. It is only a few weeks since we first heard of an institution called the Central London Throat and Ear Hospital, which it appears for more than a year had been hiding its light under a bushel "in unpretentious hired premises in Manchester-street, Gray's-inn-road." But this notwithstanding, so successful had been its operations that the committee determined to try a more ambitious flight, and have accordingly obtained a site in Gray's-inn-road whereon to build a real hospital, the first stone of which was laid last week by Madame Adelina Patti, assisted by many members of the musical world. Of course we have not a word to say against the eminent artiste whose great reputation and influence have been made use of to lift into prominence this obscure institution. If it were not for the clue given in the report in *The Times* of the ceremony of laying the foundation-stone, we should be at a loss to understand how she and her friends were ever induced to countenance the undertaking. We learn, however, that one of the surgeons—the chief surgeon, in fact—of the hospital is also surgeon to the Royal Society of Musicians, and it is therefore within the range of possibility that this gentleman may, through his connexions with the Society of Musicians, have enlisted the sympathies of the members of the Society in this little scheme. Be this as it may, we again strongly protest against the spread of these special hospitals. Specialism is becoming a plague-spot in the profession. But so strong is the current in favour of specialism and its self-elected professors, that even respectable newspapers are carried away with it. *The Times*, in the report already referred to, actually goes out of its way to discuss the question of special hospitals, and attempts to draw a lively picture of the great benefits likely to be conferred on humanity by the use of the laryngoscope and the ophthalmoscope, provided only that these instruments be placed in the hands of none but specialists. In *The Times*, we are told that "The stethoscope is an instrument of different character, which is used by the profession generally." The writer should have known that of all the apparatus employed in the physical examination of diseased persons, there is none more simple in its employment than the laryngoscope. Next to the laryngoscope comes the ophthalmoscope, whereas by universal consent, at least by the consent of those competent to form an opinion, the most difficult to use of all such apparatus is the stethoscope. By this we do not mean the mere placing of one end of the stethoscope to a patient's chest and the other end to the physician's ear, but we mean the interpretation of the multitudinous and complex sounds of morbid and even healthy respiration. We do not hesitate to affirm that where there are twenty students who will make an accurate diagnosis with the laryngoscope or ophthalmoscope, there are not three whose opinions on the physical signs of a chest are trustworthy. And yet a special throat hospital can succeed in securing the sympathy of the distinguished persons who took part in laying the foundation stone of the Central London Throat and Ear Hospital. If the Society of Musicians can be brought to take such an interest in affections of the throat, we may expect soon to see some of the more ambitious of its members establishing a "Hospital for Asthmatic Pipers," or a "Home for Distressed Fiddlers."

Seriously, it is time that the profession generally should take up the grave and pressing question of the multiplication of special hospitals, and the *raison d'être* of every hospital that it is proposed to establish.

LEPROSY IN INDIA.

We are very sorry to discover the attitude which the Government of India has assumed towards the question of the etiology of leprosy, and the general management of lepers in India. We had hoped that Dr. Vandyke Carter would have been permitted to continue his researches in reference to the disease, and by the aid of special official facilities accorded to him. The Indian Government, however, has not merely declined to act upon the suggestions that Dr. Carter should be appointed a Special Leprosy Commissioner—a refusal we can well understand from a red-tape point of view—but has decided that Drs. Cunningham and Lewis are to be available to take up the microscopic and scientific portion of the inquiry, whilst general facts are to be collected and dealt with by the sanitary commissioners of the country, aided by the civil surgeons in their capacity of health officers; thus, it seems to us, elbowing Dr. Carter out of any participation in a matter upon which he has thrown great light by honest and admirable work. We have persistently objected for years past in reference to leprosy to this piecemeal mode of investigation by a multitude of different workers, of varying ideas and degrees of competence, operating through the cumbrous machinery of an already well-occupied department sanctioned afresh by the Government. Our contention has been that one or two competent investigators, working steadily at the subject over a wide area, would be much more likely to succeed in gathering together reliable facts. Probably, as Dr. Carter's views in reference to the general treatment of lepers turn out to be not in accord with those of the Government, it may be convenient to deny Dr. Carter any facilities for prosecuting his inquiries any further. The Government of India expresses itself as disbelieving in the power of segregation, which Dr. Carter advocates, to diminish the amount of leprosy in a country. It remarks that there are 100,000 lepers in India, and the Government "could not undertake to build hospitals for all these people, and to keep up establishments for them, to clothe and feed them, and practically to turn them into sick paupers. To say nothing of the enormous cost which these measures would entail, the difficulties of attempting anything of the kind are insuperable." The Government does not show that segregation would not be effectual if properly carried out; it presents the matter solely in the light of a financial difficulty, though we altogether doubt if the difficulties of adopting segregation would be so great as the Government imagines. Whether it would do all that its advocates affirm of it is another matter.

We further notice that the Government of India, in the memorandum which it has printed on this subject, states that "segregation commends itself to those who believe that leprosy is in some way or other contagious." But segregation is advocated by many modern authorities who disbelieve the contagiousness of leprosy, on account of the hereditary character of the disease, and with the view of preventing its propagation from parent to offspring.

EFFLUVIA AND INFECTION.

EVER since an unfortunate return made by the Registrar-General or some officer of health, a few years ago, informed the public that the London "nightmen" were exceptionally free from disease, there has been a growing contempt for bad smells. It was forgotten that robust constitutions alone could resist constant exposure to the noxious exhalations from sewage in process of emptying the old-fashioned cesspools; and therefore if there were "nightmen," they must needs be peculiarly strong men. This tolerance of nasty effluvia may be a convenient acquisition, especially for those who regard it as a duty to pass some weeks annually in continental towns and watering-places, whither our own sanitary authorities have just sent a commission to pick up suggestions for improved management at home. But it must not be wholly lost to memory that bad smells are the warning signals nature holds out in token of danger. They may not be identical with the causes of disease. The morbific germ may be, and no doubt often is, present where there is no warning odour; and an abominable stench may be comparatively harmless. It is nevertheless a general truth which cannot be safely disregarded, that an offensive smell is an indication of impurity likely to be poisonous. No one would suppose this truth was even formally recognised amongst us, judging by the disgracefully neglected state of our public "conveniences." Those in the streets are unaccountably horrible. In some cases the ammoniacal and other emanations are overpowering. The condition of matters at the theatres is even less endurable. In more than one instance passing to a box or stall in the neighbourhood is a feat scarcely less disturbing than a troubled sea-passage across the Channel. It would seem that nothing more could be necessary than to call the attention of the vestries and managers of theatres to these evils in order to ensure a remedy. Unhappily that is not the case. Local authorities are imperturbable; inspectors of nuisances appear to lack the sense of smell; while everybody connected with theatres and places of public entertainment, from the architect who plans and builds them, to the functionary who performs infinitesimal services for large fees, appears to be imbued with the belief that to pass three or four hours in an atmosphere heated so as to be barely respirable, and surcharged with carbon, sulphur, and ammonia in all their combination, together with the nastiest and most noxious organic vapours, is an integral part of the price they are entitled to exact from the public in return for their amusement. It is not the slightest use to reason with these people, and vain to entreat them. But it becomes a duty just now to warn persons, and particularly the heads of families, returning from the seaside and the country, and therefore highly susceptible to noxious exhalations of all kinds, that it will be only prudent to take special precautions.

LUNACY REPORTS.

IT is a moot question just now—perhaps rather curious than practical—whether the apparent increase of mental disease in certain districts may not be due to the undoubted fact that a larger proportion of cases are brought under official notice and sent to asylums than in times past. It seems probable that this reassuring view of the situation is in part justified. More intelligent attention is happily bestowed on the subject of insanity than it formerly received. Science has begun to dispel some of the clouds which have so long obscured the province of psychology. Disease of the mind is beginning to be recognised as an affliction to be relieved, and perhaps cured, by medical treatment. As this salutary change progresses in public opinion it is only natural that the friends of persons mentally unsound should place them under a curative *régime*, and what was hid away in dark corners as an indelible family disgrace should be more promptly and hopefully disclosed with a view to remedy. It is also gratifying to find, as we pointed out last week, that the study of this neglected but promising subject is about to receive express encouragement at the hands of the great examining bodies. Meanwhile what the profession and the public are most deeply interested to secure are fuller information and a better classification of cases, based upon their nature and origin. It is, of course, the acute forms of mental disease that attract most urgent attention, and these are the varieties of the malady that appear on the increase. In the busy centres of life—the great cities—acute cases abound, while the chronic forms are most common in rural districts. In part probably this may be accounted for by the circumstance that persons afflicted with the less violent varieties of insanity are generally withdrawn from the scenes of hurry and excitement, either laid aside as useless, or sent away in the hope—too often disappointed—of benefit from temporary retirement. It is most desirable this erroneous and alarming view as to the increase of mental disease should be rectified. Nothing is more apt to work mischief than a mistaken fear of evil consequences likely to be brought about by mental activity at a time when such activity is indispensable. It would tend to clear away a fog of error if we could obtain more full and accurate information as to the habits, temperament, and the immediately antecedent circumstances of persons newly attacked. Speaking generally, we believe it would be found that the dismal ranks of the incurably insane are recruited from the multitude of purposeless loiterers or spasmodic enthusiasts in life, rather than the steady earnest workers. Again, a great deal more stress than appears either requisite or desirable is laid on the influence of what is called "an hereditary tendency." A process of following out the history of families from parent to child, in place of tracing it backwards with a foregone conclusion, might yield more satisfactory results. The number of persons who enjoy and preserve perfect mental health, in spite of a "tendency," is probably incomparably greater than that of those who are supposed to fall victims to this misfortune. Such matters, together with a more precise knowledge of the class of cases most easily or frequently cured, can only be elucidated by efficient and thoroughly impartial returns. These, we regret to find, are not forthcoming. Time is, no doubt, needed to develop an exhaustive and definitive method of reporting mental disease, but we fail to see the gradual improvement which ought from year to year to be noticeable in the returns edited by the Lunacy Commissioners. The subject is one of extreme urgency and widespread importance. Figures are all very well, but we want *facts*. To be really serviceable these must be laboriously collected, and classed and compared with a degree of scientific accuracy unfortunately conspicuous by its absence in the returns and reports at present available.

EXPERIMENTAL RESEARCH ON THE TOXIC PRINCIPLE OF PUTREFYING BLOOD.

V. Feltz employed in his investigations on this point blood which had been exposed to the air for several months. Microscopic examination, undertaken from time to time, demonstrated that the mobility of the spirilla and vibriones progressively diminished, and they ultimately disappeared entirely. The bacteria and the zooglœa membranes resisted putrefaction for a longer period, but likewise lost their mobility, and finally nothing could be seen in the fluid but a confused and motionless mass of rods and granules. Coincidently the smell of the blood became less pungent, and the production of ammoniacal compounds diminished. An injection being made of such putrescent blood (in quantity amounting to two cubic centimetres) into the veins of a dog, the phenomena of infection appeared, as evinced by elevation of temperature, loss of appetite, vomiting, bilious and even bloody evacuations. Four of the animals died in the course of ten or twelve days, but two others recovered completely. Old putrefied blood, in which no trace of life could be discovered, exhibited the same toxic action as that in which germs and fungus seemed to be in full activity, and it would appear that the septic action must be referred to some chemical agent which results from the presence and perhaps from the decomposition of the organisms, but is not due to the organisms themselves. On the other hand, the blood of the animals thus poisoned by decomposing blood exhibits numerous bacteria and cocco-bacteria, notwithstanding the fact that no living germ is present in the blood injected. Putrid blood which had stood for five months in the sun, and which had acquired a doughy consistence from evaporation, was perfectly dried in the air-bath and rubbed down to a fine powder. The impalpable powder was mixed in small quantity (one-half c.c.) with two to three c.c. of water, and this was injected into the crural veins of three powerful dogs. The animals immediately exhibited marked depression. After four or five days febrile symptoms were established, with bilious and bloody diarrhœa, vomiting, and biliary urine. Two of the three dogs died after ten days. The blood contained bacteria, and the red blood-corpuscles showed the well-known changes in form and disposition to break up exhibited by those of animals infected with septic blood. Nevertheless, the most minute investigation failed to reveal the existence either of living bacteria or vibrios in the dried powder either before or after its mixture with water. Now, since blood at all stages of putrefaction, till it has even undergone complete desiccation, after a certain period of incubation, induces septic phenomena, we must admit, according to Feltz, that motionless and apparently dead germs are present in the injected fluid, which, when thrown into the healthy blood, return to life, and are capable of reproducing the septic condition.

YELLOW FEVER.

The Annual Report of the Marine Hospital Service of the United States for the past year, compiled and presented by Dr. John M. Wordworth, Supervising Surgeon, contains some useful particulars as to this disease collected during the epidemics of 1873 and 1874 at New York, Pensacola, and elsewhere. The latter epidemic, which appears to have been comparatively circumscribed, was, as on previous occasions, the result of importation. The disease was brought to the quarantine station by a Spanish vessel, the first victim being a man who was engaged in the hold removing ballast, at a time when, for several days, the thermometer had averaged 78° Fahr. This vessel propagated the disease to another ship that was placed next to her in quarantine, having arrived with a perfectly healthy crew. (So much for quarantine!) Three men working at the quarantine station were next attacked, and afterwards the crew of a lighter, detained in quarantine five days, but also healthy on arrival. These men took the disease ashore. It lapsed for a time, but another case was admitted from without, supposed to be suffering with Chagres fever, and from that time (13th of August) to the middle of December, the disease was epidemic at Pensacola. The total number of cases that occurred was 225, with 55 deaths—i. e., a mortality of nearly 25 per cent. Among the 43 cases admitted to hospital within the first forty-eight hours of attack, 2 deaths occurred. Both of these men had been drinking hard immediately before the seizure; one also had scurvy, and the other pulmonary mischief. Of the 51 hospital entries, there were 42 recoveries and 10 deaths, and Dr. J. S. Herron, surgeon in charge, after an experience of three epidemics (in 1867, 1873, and 1874), records the opinion that, if patients are seen and treated within thirty-six hours after the commencement of the attack, the mortality need not exceed 10 per cent. for hospital, and 5 per cent. for civil practice. There was in this last epidemic a strong typhoid tendency, and less constipation than usual. In addition to the ordinary symptoms, most of the patients were on the third or fourth day covered with an eruption resembling lichen tropicus, and convalescence was followed by desquamation of the cuticle. The disease was introduced from Cuba, and the history of its propagation shows, in a most marked degree, not only the uselessness, but the eminently mischievous effects of quarantine, as carried out at Pensacola.

Dr. Frank W. Reilly, in reviewing the epidemic of yellow fever in the States during 1873–4, discusses elaborately the subject of quarantine, and reports in effect that it might be so carried out as to exclude the disease. But inasmuch as this process means, practically, annihilation of commercial interests, an intelligent and well-managed sanitary supervision, examination, and isolation at the various ports offer the best and most efficient substitute. The portability of the poison is once and again, in this last epidemic, proved most indubitably, and the important fact is stated that exposure to a temperature of 32° F. completely destroys it, though it may remain for an unknown length of time in a quiescent state when not subjected to a freezing temperature, or exposed to conditions necessary to its multiplication. Dr. Reilly says: "I consider the most reliable method of disinfecting a ship is to batten down her hatches and reduce the temperature of her hold to 30° F., and to keep her in that condition for four or five days, so that the bilge-water may remain frozen for that length of time." During the epidemic, 15,410 cases occurred in the States, 3397 of which were fatal.

Port sanitary authorities in this country are not likely to be called upon to deal with this disease, in consequence of the temperature required for its development; but this report is noteworthy, as regards general sanitation afloat, because it shows the spread of an international feeling against a quarantine of exclusion, which is impracticable, and a quarantine of prolonged detention, which is useless.

SAILORS' DWELLINGS AFLOAT.

It would possibly have been *mal apropos*, but it would most assuredly have been useful, if the Artisans' Dwellings Act just passed had included some provisions for sailors' dwellings afloat. The Merchant Shipping Act of 1867 did something to improve the condition of these places, enacting that every seaman shall have appropriated to his own use "not less than seventy-two cubic feet and twelve superficial feet, securely constructed, properly lighted and ventilated, properly protected from weather and sea, and, as far as practicable, properly shut off and protected from effluvium which may be caused by cargo or bilge-water." We are reminded of the unsatisfactory results of this piece of legislation by looking over the last half-yearly report issued by the City Corporation as Sanitary Authority of the Port of London, by which it appears that in forty-three cases the quarters of the crew were found in an ill-ventilated state, and suggestions for their improvement made by the officers of the sanitary authority were adopted. It is, of course, evident enough that the Marine Department of the Board of Trade, as their arrangements are at present constituted, have no means of judging whether the clauses of the Act above quoted are carried out in their integrity. Anyone who cares to take the trouble may visit vessels in the port of London, the accommodation given to the crews of which is not fit for dogs or pigs. Last year three men were killed (i.e., suffocated) by the effluvium arising from a foul cargo shipped at Barking, and it was found that they were lodged in a miserable lower forecastle, on a level with the freight, and barely separated from it by a decidedly fragmentary bulkhead. In these and analogous cases, as the law now stands, the Port Sanitary Authority can only suggest, and cannot enforce, structural alterations. The Merchant Shipping Act provides legislation which, in this particular, as in that relating to medical inspection of seamen, is a dead letter. There is a report now before us, headed "The Hygiene of the Forecastle," contributed by Dr. Heber Smith to the last Annual Marine Hospital Service Report of the United States, which entirely endorses all that we have recorded about homes afloat. It contains two or three very correct sketches of ships' forecastles, which show that they are, as the author says, "the neglected point of sanitary police." And a little book called "Modern Naval Hygiene," by Dr. Leroy de Merecourt, translated from the French by Staff-Surgeon John Buckley, of H.M.S. *Endymion*, speaks most emphatically on the importance of paying special attention to this important subject. All lower forecastles in vessels of less than 300 tons should be abolished. It is impossible to ventilate them sufficiently; there must always be an unhealthy, and sometimes a dangerous, proximity to the cargo, and the hatchway is usually so arranged that in the event of a collision or other accident near the bows a complete blocking up of all means of exit may occur, and indeed has frequently occurred, and the unfortunate sailors below have been drowned simply because they were imprisoned in their berths. In large steamships with lower forecastles, employed on telegraph and other works in equatorial latitudes, it is very desirable, on the score of temperature as well as cleanliness, to substitute hammocks for bunks. The entire space can then be cleared and cleaned without difficulty, as no holes and corners exist for the lodgment of foul material. In ships with large upper or topgallant forecastles it is better to have the bunks ranged amidships than along the sides of the vessel. These suggestions are sufficient to show that more attention should be paid to the condition of sailors' dwellings afloat. Shipowners are, as a rule, glad to adopt suggestions that are found to be practicable and useful, as instanced in the number of changes effected in vessels on the Thames during the past year through the agency of the port sanitary authority. In any future legislative changes the responsibility of the work should be more definitely fixed. As matters now obtain, the Board of Trade legislate, but know nothing about the results, and the local authority are bound by law to visit and inspect, but cannot, except in very gross cases of insufficient accommodation, legally compel structural changes to be carried out.

THE MEDICAL OFFICER OF ST. GEORGE'S, HANOVER-SQUARE.

The Guardians of St. George's Union cannot be congratulated on the way in which they have ended the inquiry into what we suppose we must call the charges against Mr. Fenton. The principal of these had reference to Mr. Fenton's behaviour in regard to an order to attend a man named Callagahan who died before Mr. Fenton's call, though the evidence showed that Mr. Fenton called very soon after the order reached him. The case was investigated by a jury. By the way, it is gratifying to put on record the case of one jury which was noble enough to refuse to censure a medical man because he was absent. But they received some garbled information, which led a contemporary unfortunately to publish a paragraph headed "Charge against a Parish Officer." This paragraph was referred to the guardians by the Local Government Board for inquiry. Another charge had reference to the case of a man named Murphy, and entirely broke down. As Mr. Fenton was able to show that he went almost directly to the man Callaghan, we should have thought that the guardians would be only delighted at the triumphant defence of their medical officer, and straightway have recorded their satisfaction. Viscount Pollington, with several other guardians, seemed anxious to pass a motion approving the conduct of Mr. Fenton. But the guardians were not equal to such a gracious course, and contented themselves with the following resolution:—"That no further steps be taken with regard to the charges against Mr. Fenton unless they are considered necessary by the Local Government Board." This is a virtual admission of the unfoundedness of the charges, and not Mr. Fenton, but the board must suffer in public estimation by the event. We congratulate Mr. Fenton on his defence. We will not justify every word of it, or some terms in which he characterises a medical member of the board, or his letter to a magistrate on the mental condition of a neighbour. But he has triumphantly repelled the chief charges brought against him, and shown that they should never have been brought. The frequency with which such a result follows charges of this kind will surely tend to make them less common.

RECENT METROPOLITAN AND PROVINCIAL URBAN DEATH-RATES.

During recent weeks the death-rate in London has more than once been lower than in any of the seventeen large provincial towns for which weekly returns are published. The Registrar-General, in his last weekly return, especially notices this fact, and states that whereas the annual death-rate in London, with its estimated population of 3,445,160 persons, during the week ending the 18th inst. did not exceed 20 per 1000, it averaged 27·2 in the seventeen other large towns, the aggregate population of which is estimated at 3,286,873, or rather less than that of the huge metropolis. The acceptance of the general death-rate—that is, the proportion of deaths to population—as a test of the health or sanitary condition of a community has, it appears to us on insufficient grounds, been frequently called in question; it may, therefore, be well to notice the recent death-rate in London and in the seventeen provincial towns from epidemic or preventable diseases. During the week ending the 18th inst. the annual death-rate in London from the seven principal zymotic diseases was equal to 4·9 per 1000, of which 2·2 was due to diarrhœa, principally infantile; in the seventeen provincial towns the zymotic death-rate averaged 8·3 per 1000, and the diarrhœa-rate was 5·0. Thus the fatality from zymotic diseases in seventeen of the largest provincial towns exceeded that in London by 70 per cent., and the fatality of diarrhœa was more than twice as great. Infant mortality, too, in the provincial towns compared most unfavourably with that in London. There is no reason, therefore, to believe that the general death-rates quoted above, which point to a recent far lower standard of health in our large provincial towns than in London, are to any considerable extent delusive. It may be mentioned that the health of London just now is not, for the time of year, exceptionally favourable, as the mortality from both scarlet fever and whooping-cough has been for some time above the average. Neither is the health of the seventeen other large towns exceptionally unfavourable, although scarlet fever is fatally prevalent in Bradford and Bristol. It is, indeed, impossible to avoid the conclusion that London has had a good start in the race for sanitary improvement, and that our other large towns have much lost distance to make up.

DUTIES OF JURORS.

The jury empanneled to ascertain the "cause of death" in the case of alleged poisoning by strychnine at Norwood displayed more than common spirit in an extraordinary fashion. The foreman and certain independent members of the judicial twelve took the matter out of the hands of the coroner, and proceeded to examine the witnesses in their own way, and to their hearts' content. They inquired into the existence and credibility of rumours, they expounded their views as to how the alleged crime might have been committed, and generally conducted the investigation in a fashion at once original, and, to the outside public, probably entertaining. It is impossible to give higher praise to their proceedings. We are not sure that the business of the coroner's court is generally transacted in the manner best calculated to assert the majesty of the law, or to maintain the dignity of its local administrators, but this new method of practically deposing a coroner in his own court, and making the jury supreme, is one which certainly strikes us as inconvenient, and likely to produce dire confusion. There can be no question as to the expediency of making the inquiry into a cause of death as inquisitorial as may be consistent with law and justice; and it is, perhaps, necessary that more latitude should be allowed to both judge and jury in such a court than is either requisite or wise in the case of a court of law; but there must be rules of procedure, and to the practice enjoined by custom coroners, jurymen, witnesses, and all concerned should submit themselves. It would be a great evil if these courts were reduced to a lower status in public opinion, and permitted to sink below the point of dignity their present condition implies. We are not sure that they would bear depletion in either respect without consequences so serious as to be fatal to their repute, perhaps to their existence. Indeed, we would go so far as to hint that coroners might with advantage keep a more jealous watch over the conduct of their courts, and emulate the business-like earnestness and dignity of tribunals to which they need not be vastly inferior, although they are tributary.

CUCURBITACEOUS ANTHELMINTICS.

Some investigations have recently been made by M. Heckel into the active part of pumpkin seeds. These seeds have been much used of late for the expulsion of the tapeworm, for which purpose they were employed in the early part of the last century. The mode of their administration has hitherto been to give the bruised seeds in large quantities suspended in water, the outer envelope only having been removed. About two ounces of the seed was the ordinary dose. It is probable that so large a quantity contains much inert matter. Some recent observations apparently indicate that the active principle is contained only in the embryo. To ascertain whether this is the case was the chief object of M. Heckel's observations. He first administered, in two cases of tænia, about six ounces of the perisperm, tegumentum and testa, a purgative of castor oil having first been administered. The tapeworm was not expelled in any case. In two other cases the membrane surrounding the embryo was given—about half an ounce,—preceded and followed by a dose of castor oil. In each case the tapeworm was expelled entire. Subsequent experiments yielded the same result. This membrane was then carefully examined, and found to consist of two membranes separable by maceration in water. The outer membrane contained a resin in small quantities (one in seventeen), which M. Heckel believes to be the active agent. He believes that the castor oil acts not only by its purgative effect, but by dissolving the resin and rendering it active. The second membrane contained more chlorophyll than resin. It must not be forgotten that these seeds contain a fixed oil, to which their qualities have been ascribed, and which may be obtained by cold expression from the seeds in the proportion of half an ounce to a pound. This oil has been used with success, in repeated half-ounce doses, in cases of tænia.

THE HOME OF THE COSTERMONGER.

We hear that there is some prospect of a new stack of Peabody buildings being erected in the very heart of that vile rookery which lies between Lincoln's-inn-fields and Drury-lane. It is one of the very worst of the London slums. The greater number of the houses in it are in an infamously insanitary condition, and are a standing disgrace to our municipal authorities. We have ourselves repeatedly drawn attention to the dismal district, and urged the importance of reform. But it must not be forgotten that reform in such a matter is in some senses a dangerous as well as a difficult operation. The population of such a district as this is often of a most complex character, its members agreeing only in the one peculiarity of the direst poverty. Burglars, pickpockets, and utterly worthless vagrants are huddled cheek-by-jowl with costermongers, porters, labourers, "supers," and a thousand nameless outsiders of London life, a vast proportion of whom are honest and would be decent if they could. Now all these people, even the thieves, must live somewhere, and the Peabody-buildings—excellent in their way—are absolutely unfit for, and inaccessible to nearly all of them. A vast number of them are obliged to live in the neighbourhood, and the only effect of pulling their houses about their ears would be to huddle them more and more closely together, and so increase the moral and physical evils of overcrowding. A correspondent of the *Weekly Dispatch*, writing evidently with unusual practical knowledge, draws particular attention to the case of the "costers." These laborious and generally honest caterers for the London poor require accommodation not only for themselves but also for their donkeys, and small surplus stores, often somewhat unsavoury, of yesterday's fish, fruit, and vegetables. So with the vendors of baked potatoes, coffee, and chesnuts. Peabody-buildings would be useless for such as these, even if they were accepted as tenants, and it seems hard that they should be stamped out in the interest of their far more powerful and prosperous brothers, the skilled artisans. Rebuilding is urgently necessary throughout the whole district, but it is a question of the utmost gravity whether the new buildings to be erected should not be made more suitable for the wants of the eccentric population around than the imposing piles which have arisen in other parts of London.

THE ROYAL BENGAL TIGER.

DR. FAYRER, who will accompany the Prince of Wales to India, has just published a little book entitled "The Royal Tiger of Bengal," which contains a map showing the geographical distribution of that animal, and a very spirited illustration of his appearance. As his Royal Highness's suite is composed largely of sportsmen, the issue of such a work is very opportune. Dr. Fayrer is not only a *savant*, but a mighty hunter, and is therefore enabled to describe the most powerful of the feline tribe from a sportsman's as well as from a field-naturalist's point of view.

Dr. Fayrer has, rifle in hand, met the tiger in his native swamps and jungles times out of number, and occasionally had a narrow escape from the claws of the brute. He describes his experiences in a graphic and interesting manner. "Those who have seen the tiger when stripped of his skin," says the author, "can hardly fail to have been struck with the grotesque resemblance to a gigantic human form which is presented by his sinewy and muscular frame as the arms are stretched out on either side. The vast shoulder, arm, forearm, wrist, and hand have a wonderfully anthropoid appearance." These muscles are modifications of those in the human or other mammalian limbs, and attain their excessive development in obedience to the necessities of the creature's existence. As is generally known, the wounds made by the fangs and claws of a tiger are extremely dangerous, although some wonderful cures have been reported.

THE PILLARS OF THE DIAPHRAGM.

MUCH attention has been given to the function of the vault of the diaphragm, but very little to that of its pillars. The action of the pillars of the rabbit's diaphragm has, however, been recently studied by M. G. Carlet. If the abdomen of a living rabbit is opened, and the liver and intestines turned to one side, the pillars are seen distinctly to contract, but simple observation is insufficient to decide whether this occurs before, during, or after that of the vault of the diaphragm. If the contraction occurs before that of the diaphragm, their function will be to fix the centre of the diaphragm, in order to permit the contraction of the arch. If this contraction succeeds that of the rest, their action will be to depress still more the vault of the diaphragm after it has been lowered by the contraction of its peripheral portion. An experiment to determine this could not be made with advantage in most of the mammalia on account of the interlacement of the muscular fibres of the two portions of the diaphragm. In the rabbit, however, the muscle is distinctly digastric, and its two portions are continuous only by the central connecting aponeurosis. M. Carlet made a longitudinal incision in the axis of this tendon, and thus obtained a button-hole-like slit, of which one edge was in connexion with the muscular fibres of the vault, and the other with those of the pillars. The two lips of the slit were uniformly separated and approximated simultaneously so as to imitate the movement of a mouth which opens and closes, presenting an elliptic opening when the diaphragm is relaxed, and a circular opening when the vault and pillars contract. From this M. Carlet infers, first that the contraction of the pillars and the vault is simultaneous, and, secondly, that the pillars have a direct inspiratory action.

COMBINED SANITARY DISTRICTS.

Two new combined districts are about to be formed for the appointment of medical officers of health. One will include the rural sanitary districts of Peterborough, Whittlesea, Stamford, Arrington, Caxton, and St. Neots, and St. Neots urban district. The salary attached to the appointment is £639. The other district will include the urban districts of Cockermouth and Keswick and the rurul district of Cockermouth Union; and the salary is fixed at £359 per annum. It is to be observed that some of these authorities have seceded from combinations formed shortly after the Public Health Act of 1872 came into operation. We should like to see a map of England and Wales with the boundaries of all these combinations and scrap districts, urban and rural, accurately indicated. We much doubt if a record of this sort exists even at Gwydyr House. Nothing would show so plainly the wonderful geographical muddle made during the last two years by local authorities, under the instruction and sanction of the general inspectors of the Local Government Board. Meanwhile, what with additions to and secessions from old, and the formation of new, combined sanitary districts, medical officers of health must live in a pleasing state of uncertainty both as to position and income.

CHEAP DOCTORS.

SOME medical men seem to think very humbly of the value of their services. Even in London there are medical men who contract to supply advice and medicines for a week for the modest sum of one shilling; or, if the patient is to be visited at home, half-a-crown. Perhaps the most striking instance of this "humbleness" that has come under our notice is that of Mr. Palmer, who, in announcing the discontinuance of all his medical clubs except the Stoke and Melford one, intimates in a handbill that any of the labouring classes wishing to consult him may do so on payment of *threepence*, to include advice and medicine for one person. Those wishing to be visited at home must pay sixpence. We must be permitted to question the right, speaking ethically, of any man to offer medical attendance on terms which must bring the profession into disrespect. The public, even the poor, ought to know that mere medicines cannot be supplied good and sound on any such terms. There is an unfailing connexion in regard to medicine between what is cheap and what is to be avoided. This is not the case of a well-organised club or provident dispensary, encouraging the working classes of a district to make provision, by weekly and systematic payments, for good and respectable medical attendance. Such institutions deserve every encouragement. But the case we condemn is that of offering medical services on terms which can only bring them into contempt. There may be no law against such a system, but there is a great unwritten understanding that a man owes something to the dignity of his calling.

GRUDGING MEDICAL CHARITY.

The dispensers of medical charity among the poor, either in the case of dispensaries or under the Poor Law, have to work under great disadvantages. It is painful to them to know that medical measures are so poorly supported by the general conditions of the patient. But how much harder is it to have any reason to believe that the very medicines which they prescribe are begrudged by those who represent charity. Two instances are before us. One is that of a Poor-law officer, who complains that the Dispensary Committee of his Board had a feeling that the medical officers were extravagant in the use of expensive drugs, and one member of the committee recommended that quassia should be prescribed instead of quinine. It would do this gentleman good to have ague for a week treated with quassia. Another instance is reported in the case of the Tavistock Dispensary, where Dr. Crighton has resigned because—we are sorry to say—one of his colleagues, Mr. Sleman, complained that he gave the patients too much medicine, and a committee seemed to sanction this view. It is only fair to the general body of subscribers to say that they passed the following resolution: "That having understood that Dr. Crighton has resigned, partly because a committee has seemed to sanction some reflections on his mode of prescribing, this meeting most emphatically repudiate any such seeming intention on the part of their committee, and promise to protect the physician against any interference in the future if he will kindly withdraw his resignation."

If we are to give the poor medicines let us give them the best medicines, as a matter of economy as well as of generosity. We entirely sympathise with the high-minded feeling with which both of these gentlemen resented any dictation as to the way in which they should prescribe. Indignation is a proper sentiment towards such interference, not the less so if it comes from a medical quarter. Rich people have comforts and change to restore their lost health; poor people rely on medicine almost entirely. And we would not like to characterise the feeling that would give them scanty supplies or that would substitute quassia for quinine.

CARLO BOTTA.

The medical profession has reason to be proud of the great historian whose ashes were transferred to Santa Croce at Florence on the eve of the recent festival in honour of Michel Angiolo. Born at San Giorgio del Canavese, in Piedmont, on November 6th, 1766, Carlo Botta graduated in Medicine in the University of Turin. After two years' imprisonment for advanced political opinions, he went to Grenoble, where he was appointed surgeon to one of the regiments of the Army of the Alps. He eventually settled in Paris, where he wrote his two great works on the History of America, and of Italy (in continuation of Guicciardini's). His fortunes fell so low at one time that he was constrained to sell as waste paper 600 copies of his American History to buy medical comforts for his wife. He died in Paris on the 10th of August, 1837, in comparative comfort through the bounty of Charles Albert, King of Piedmont. In transferring Botta's remains to the Pantheon, where monuments are raised to Dante and Alfieri, the Italians have done justice to the historian's power. He was a master of his language, an impartial judge, and a prophet of the national regeneration of his fatherland, to which he powerfully contributed.

"DIPSOMANIA."

How much names have to do with the formation of public opinion is well known. Many a cause has been made or ruined by an epithet, happy or unfortunate, which its friends or enemies have bestowed upon it. It is of the utmost importance that accurate and not misleading terms should become current with the public concerning any important social question. Our newspaper columns have been and still are full of illustrations of the inaccurate idea of the practice to which the term "vivisection" has spread abroad. In another column Sir James Alderson points out how inaccurately the term "dipsomania" describes the condition it is intended to designate. Of this there can be no question, but it is, we fear, too late to attempt to uproot it and to substitute for it the more accurate word which Sir James proposes. Happily, the meaning of the word is now fairly understood by the public, so that the consequences of its inexactness will be less than might at first sight appear probable. It would be long before a new expression became as popular.

HOSPITAL SATURDAY.

Captain Mercier must have found that the chair of the Hospital Saturday Fund is like anything but a bed of roses. He will perhaps begin to think it a pity that he ever took so prominent a part in initiating the separation of the Hospital Saturday from the Hospital Sunday movement. They evidently should be regarded as parts of one great attempt to gather the contributions of all classes in support of the institutions by which the sick and dying of the working classes are helped. We shall pass no further judgment on the results of the Hospital Saturday than to say that they display no evidence of the possession on the part of the committee either of the confidence of the working classes or of the knowledge of the way in which to interest these classes in the work of contributing to charities by which they are exclusively benefited. That the working men of London should in a year subscribe some £5000 only to its hospitals and dispensaries is a discredit to them, not to use a stronger word, and can only be palliated by supposing that the Hospital Saturday Committee has not their respect.

MONOBROMIDE OF CAMPHOR.

The physiological properties of monobromide of camphor have been recently investigated further by M. Bourneville, who has communicated his observations to the Académie des Sciences. His observations agree in the main with those of M. Pathault, to which we alluded a few weeks ago. He finds that the compound lessens the number of beats of the heart, and induces a contraction of the auricular vessels. It lessens the frequency of the respirations without interfering with their rhythm. It lowers the temperature regularly, and in the fatal cases this fall of temperature progresses to the end. The fall was very considerable, amounting in the cat to 15° Cent. In the cases which recovered the fall in temperature was succeeded by a rise which continued until the normal or natural point was reached, but a much longer time was occupied in the rise than the fall had taken. The monobromide of camphor was found to possess undoubted sedative properties. It produced no digestive disturbances, but its continued use led, in cats and guinea-pigs, to a rapid loss of flesh. It has been found useful in cardiac affections of nervous origin, in asthma, cystitis, and cases of epilepsy in which the attacks occurred simultaneously with attacks of vertigo.

THE EVILS OF THE COUNTER.

PUBLIC attention has been called by Mr. Fred. Smith of Leeston, near Weston-super-Mare, to the hardship inflicted on young girls in compelling them to stand behind the counter for eight, ten, or twelve hours daily, without opportunity of sitting down in leisure moments. The practice is unquestionably a frequent cause of physical weakness of a serious character. The hours of standing are continued from day to day and week to week, through periods when to many the exertion and the erect posture are sources of great suffering. The need for such rest as opportunity renders possible is, we are glad to believe, recognised in a large number of houses of business. It should be in all, and it is a disgrace to the humanity of employers that a public demand should be necessary before the requisite arrangements are generally conceded.

THE BRITON LIFE OFFICE.

WE publish in another column a report of the Briton Medical and General Life Association, issued at an extraordinary meeting held last Tuesday. As is pretty generally known, the profession is greatly interested in the success of this Office, nearly 3000 medical practitioners being connected with it. It is therefore to us a source of sincere pleasure to read the satisfactory financial statement now made, and which will doubtless remove any prejudice against the Office created by the recent attacks made on its stability. With the new series a large influx of fresh business is anticipated. We are given to understand that the same liberal arrangements as regards fees paid to medical men will be maintained.

COTTON-WOOL FOR SURGICAL DRESSINGS.

AT the last sitting of the Paris Academy of Medicine the question of cotton-wool for surgical dressings was again debated, with the result of showing the beneficial effects of that mode of dressing. Both Professor Gosselin and M. Alphonse Guérin spoke most highly of the good results they had obtained. They were not agreed, however, as to the cause of the excellent properties of wadding applied to wounded surfaces, M. Guérin believing that it was due to the interception of germs by the cotton-wool, and M. Gosselin referring it to the warm, even, comfortable temperature kept up by the cotton-wool.

DEATH OF DUCHENNE DE BOULOGNE.

IN our last issue we mentioned the illness of Duchenne de Boulogne. We now have to record with regret the death of this celebrated physician, whose researches on the nervous system and the medical applications of electricity are universally known. Duchenne had a stroke of apoplexy about three weeks ago, from which he partially recovered, but which has ended in destroying his life. In our next issue we shall notice more at length the career of the indefatigable and talented worker, who laboured to the last, and whose energies neither fortune nor success nor age ever diminished.

THE INTERNATIONAL MEDICAL CONGRESS AT BRUSSELS.

ON Monday last the formal inauguration of the Brussels International Medical Congress took place in the Ducal Palace, and in the presence of the King. Mr. Vleminckx, President of the Brussels Academy of Medicine, took the chair, supported on his right by M. Delcour, Minister of the Interior, and on the left by M. Anspach, Burgomaster of Brussels. Several speeches were made on the occasion; one by M. Vleminckx, another by M. Delcour, and a third by M. Anspach, which terminated the sitting.

IT is seldom we have to record anything in the nature of a "strike" in our long-suffering profession. Symptoms of revolt, however, occasionally appear when the burden has been laid on too heavily, as, for instance, when a man has to administer to the medical wants of a Poor-law district of 50,000 square acres or so for the munificent sum of £20 per annum, or less. Last week the Carmarthen Board of Guardians received a memorial from six medical officers of the union asking for an increase in their salaries, with an intimation that if the request were not granted they would resign. Consideration of the matter was postponed for a fortnight. We hope the most obtuse guardian or vestryman in the kingdom will concede that six members of an honourable profession would never combine in this manner to rectify their wrongs unless they had sufficient grounds of complaint.

WE have to record this week the death of Mr. G. L. Cooper, F.R.C.S., which took place on the 17th inst., at the age of sixty-five. Mr. Cooper was the nephew of Samuel Cooper, F.R.S., the author of the well-known Surgical Dictionary. The subject of our notice, after studying in London and Paris, obtained the M.R.C.S. in 1834, and was admitted a Fellow a few years later. He was surgeon to the Bloomsbury Dispensary, and a teacher of vaccination at University College Hospital. Mr. Cooper had contributed several articles to medical literature.

IN London last week 1338 deaths were registered, including 15 from measles, 82 from scarlet fever, 9 from diphtheria, 50 from whooping-cough, 24 from different forms of fever, and 147 from diarrhœa. Different forms of violence caused 53 deaths. A death from hydrophobia was recorded at St. Thomas's Hospital. The mean temperature during the week showed a marked excess upon the mean for the corresponding period in the last sixty years.

AT the meeting of the University Court of St. Andrews, held on Wednesday, Dr. James Bell Pettigrew, F.R.S., &c., Lecturer on the Institutes of Medicine at the Royal College of Surgeons, Edinburgh, was unanimously appointed to the Chair of Medicine in the University, vacant by the death of the late Dr. Oswald Home Bell. Mr. Adam Wilson, M.A., Classical Master in the Dundee High School, was appointed Classical Examiner.

THE Charing-cross Hospital is now undergoing important alterations and additions, which when completed will nearly double the present accommodation of the institution. A sum of £13,000 will be expended in the work of enlargement, which comprises the erection of an entirely new storey. It is stated that the hospital will be temporarily closed to all save very urgent surgical and medical cases.

IT is reported that cholera has attacked the troops now stationed in Lucknow, and that it was found necessary to send the 65th Regiment some distance away. These periodical outbreaks of the disease among our soldiers seem to be inevitable. As far as we can learn, the civil population has not suffered in any appreciable degree.

A CORRESPONDENT writes to complain of what he terms the "intolerable stench" from the Tottenham Sewage Works and from the river Lea, and wants to know whether the medical officer of health for the district cannot interfere to remedy the evil.

We regret to have to record the death of Dr. William Richardson, of Kilburn, at the age of sixty-four. The deceased gentleman was M.D. of St. Andrews and M.R.C.P. London. He was the author of a book entitled "Remarks on Diabetes and its Treatment."

The *Army and Navy Gazette* states that Brigadier-General Campbell, C.B., has been compelled to run away from the War Office in consequence of the extremely foul condition of the atmosphere in the establishment.

The will and codicil of the late Mr. John Churchill, the well known medical publisher, were proved on the 6th inst., the personal estate being sworn under £60,000.

The *Pall Mall Gazette* states that several ships have recently arrived from the East with cases of scurvy on board.

Correspondence.

"Audi alteram partem."

"DIPSOMANIA."

To the Editor of The Lancet.

Sir,—The greatest of all our evils in the present day, the fundamental cause of all crime and misery, intoxication, is naturally the most frequent subject of discussion. It is to be lamented that the scientific term used in the discussion is neither accurate nor applicable. The word "dipsomania," by which the effects of excessive indulgence in spirituous liquors are meant to be described, is a mere euphuism, unworthy of the grave importance of the subject which it is meant to elucidate. If it is at all desirable to use a Greek word for an evil condition of modern society it should at least be accurate, and not, as now, be unintelligible even to the nation from whom the term is borrowed. Dipsomania, literally construed from the Greek, means "madness induced by thirst."[*] Now it is not thirst which induces the evil habit of drinking. People fall into the terrible condition of drunkenness, not by the desire to assuage thirst, but by compliance with a sensual gratification of tasting spirit, and for the enjoyment of obliviousness and relief from painful or troublesome feelings. In the case of the beer-drinkers there may be some sense of thirst to be alleviated, but it is not this class who suffer from maniacal excitement. The hideous, crying source of crime and misery is, indulgence in spirituous liquors. The Greek word for inebriety is Μέθη. "Methomania" would, in regard to classical derivation, be the correct word, and it would be comprehended by every modern Greek. The Greeks of the present day have a saying, *Μέθη μικρὰ μανία ἔτσι*—"Inebriety is a minor madness."

Your obedient servant,

Berkeley-square, Sept. 18th, 1875. James Alderson.

THE BRITISH MEDICAL ASSOCIATION.

To the Editor of The Lancet.

Sir,—It is surprising that no one has replied to Dr. Kebbell's letter in The Lancet of 28th ult., on the subject of the proposed visit of the Association to this town, since the facts so temperately related by him are most damaging, and should either be met and disposed of, or be acknowledged as ground sufficient for the abandonment of the project. The resident supporters of the invitation are warm on the subject, as is sufficiently proved by the readiness they have shown to do battle for it; their reticence therefore on this particular occasion can only be regarded as evidence of their inability to answer the letter in question.

But members who reside at a distance, and who consequently are unacquainted with the views and opinions of those concerned on the spot, might have been expected to show their interest by making inquiry into a matter that is certainly of importance to the Association. Perhaps, however, it would be fair to assume that in their minds Dr. Kebbell's statements were, after all, but the embodiment of personal views, and as such liable to the suspicion of partiality and incompleteness; and, if so, they might not unnaturally await some explanation or further evidence of their validity. If this supposition be correct, what such persons require they may easily be furnished with; it lies on the surface, and is, in short, no other than the unpopularity of the Association itself amongst us.

I forbear to occupy your space with reasons and facts in proof of this position, and, unless challenged, will content myself with the assertion that we are at once grievously disappointed in the weak and barren policy of the Association, and profoundly distrustful of the *Journal* which seems to be its only outcome.

In the local controversy on the subject, as is, perhaps, natural, a good deal of personal feeling has been evoked. But in reality all such considerations are quite irrelevant, and ought to be dismissed without further thought. It is the Association itself, as at present conducted, that is obnoxious; and that being so, no one can be surprised that we so far refuse to condone its *lâches* as to invite those responsible for them as guests in our midst.

I am, Sir, yours obediently,

R. Branwell.

Montpelier-place, Brighton, September 21st, 1875.

THE LATE DR. MAUNSELL, OF DUBLIN.

To the Editor of The Lancet.

Sir,—I think it right to inform the readers of your journal that a memorial fund is about being raised in order to show a recognition of the late Dr. Maunsell's literary services to the public, the medical profession, and especially to the Poor-law service of the United Kingdom. The desirability of such a movement was thought of immediately after his death; but some delay was occasioned by the necessity of consulting the feelings of the family. His widow, however, having consented to receive a memorial, the difficulty has been removed. We shall have a special meeting in Dublin on Friday, the 24th inst., for the purpose of starting an organisation to carry out this object. Meanwhile subscriptions will be thankfully received by Dr. Joseph Rogers, 33, Dean-street, Soho, London; Dr. Grimshaw, 13, Molesworth-street, Dublin; and by myself.

I am, Sir, your obedient servant,

28, North Frederick-street, Dublin,
Sept. 20th, 1875.
Albert O. Speedy.

The following subscriptions to the Maunsell Memorial Fund have been announced:—

Sir William Jenner, Bart.	£5	5	0
Sir Dominic Corrigan, Bart.	2	0	0
Dr. Banks	2	2	0
Dr. Robert M'Donnell, F.R.S.	2	2	0
Sir William Wilde	1	1	0
Dr. Cruise	2	2	0
M. J. Kilgarriff, F.R.C.S.I.	5	0	0
Dr. Dudley White, No. 3, North City Dispensary	1	1	0
Dr. Speedy, No. 3, North City Dispensary	5	0	0
Lambert Ormsby, F.R.C.S.I.	1	1	0
Dr. R. T. Wilson, No. 2, North City Dispensary	1	1	0
Dr. Joseph E. Kenny, No. 2, North City Dispensary	1	1	0
Dr. John A. Byrne, No. 4, South City Dispensary	1	1	0
Dr. Smyly	5	0	0
Dr. Edward Moran	1	1	0
Dr. Spencer, Burton Port, Co. Donegal	1	1	0
Dr. James Shaw, Dublin	0	10	6
E. P. Ward, No. 3, North City Dispensary	0	5	0
Dr. Edmund B. Blakely	1	1	0
Dr. Baxter	1	0	0
Dr. Atthill	2	2	0
E. S. O'Grady, F.R.C.S.I.	5	5	0
Dr. M'Clintock, F.R.C.S.I.	3	0	0
Dr. Kidd, F.R.C.S.I.	3	3	0
Dr. Grimshaw	1	1	0
Professor M'Dowel	1	0	0
Charles P. Moore, South City Dispensary	2	2	0
Dr. Churchill	2	2	0
Dr. Ross Maguire, Castleknock Dispensary	1	0	0
George Porter, F.R.C.S.I.	2	2	0
John M'Donnell, M.D., Medical Commissioner, Local Government Board, Ireland	5	0	0
R. W. S. Maybury, Queen's Bench	1	1	0
Dr. Joseph Rogers, ex-President English Poor-law Medical Officers' Association, London	2	2	0
Dr. Cameron, City Analyst	1	1	0
Dr. Peel, No. 5, City Dispensary	5	5	0
Dr. J. F. Pollock, Blackrock, Co. Dublin	1	1	0
Dr. Hyman Marks, South City Dispensary	2	2	0
Henry G. Sadler, Esq.	1	1	0

ABUSE OF MEDICAL CHARITY.

To the Editor of THE LANCET.

SIR,—A good deal has been written of late concerning the abuse of medical charity. In many instances this abuse has been perpetrated in such a manner as to put the control of it beyond the power of medical men themselves, as, for instance, that which takes place in the out-patient rooms of our large hospitals, &c. Some cases, however, appear to be connived at by our *confrères*, as in the following instance, and I should be very glad to have your opinion on it.

A patient of mine has just been spending a month at W———. She is a retired shopkeeper, and in very comfortable circumstances, perfectly able to pay me (her medical attendant) my bill as soon as it is delivered. In fact, her means may be judged of by anyone who considers that she was residing, for her own pleasure, at the seaside for a month in the height of the season. On my seeing her on her return, she told me she had been under the care of Dr. ——, as an out-patient at the W——— Sanatorium. She told me with considerable satisfaction that "it was all gratis, and she had just as good advice as if she had called at Dr. ——'s house and paid a guinea for it." I asked her if any questions were asked as to her circumstances, &c. She said, No, and added that "there were some of the patients that appeared quite ladies and gentlemen, and one young man brought his sister, who had a gold brooch and locket and a gold watch and chain."

Now, Sir, the consequence is this. My patient brings with her a prescription from this sanatorium, by which she goes on taking medicine made up by her druggist, instead of again putting herself under my care. I see that the W——— Sanatorium is founded for the relief of "diseases peculiar to women and children." Whether the medical officers consider diabetes (such is my patient's malady) to come under that category I know not; but I should like to ask you, Sir, whether you think the abuse of medical charity can be carried much farther than in the case I mention. I asked my patient how she heard of this charming charitable institution? She said she heard of it from a lady with whom she became acquainted by sitting reading near one another on the beach, and who strongly impressed upon her the advantages (particularly pecuniary) to be derived from an attendance at its out-patient department.

I remain, Sir, yours obediently,

Cirencester, Sept. 8th, 1875. EDWARD CRIPPS.

BIRMINGHAM.

(*From our own Correspondent.*)

THE medical education of women question is now causing great public excitement in this town. An influential deputation, headed by the Mayor, and including Dr. Heslop, and Messrs. Furneaux Jordan and C. J. Bracy as medical representatives, attended the last meeting of the Council of Queen's College, and strongly urged the desirability of provision being made at the College for the teaching of women students. The Mayor assured the Council that the introduction of female students would popularise the College, and that the deputation would be prepared to overcome any financial or other difficulties that might arise to prevent the realisation of their wishes. Dr. Heslop pointed out that at present ladies were obliged to go to Paris, Zurich, or America for a medical education, and that, as the general public had come to the conclusion that those women who persisted in undergoing a medical training should have an opportunity of doing so in England, it was better that the education should be given in a school like that of Birmingham, which had a reputation, recognition from the Medical Council, and all the machinery for giving a good medical education, rather than that a new educational institution for the special use of women should be started. The Rev. C. Clarke, as chairman of the Queen's Hospital Committee, expressed his belief that there was public spirit enough on the part of the board to meet, if possible, the views of the deputation, and to prevent any difficulty being thrown in the way of the admission of women to the hospital, provided the Council of Queen's College would themselves accept their co-operation. After a long discussion, an understanding seemed to be arrived at that the assent of the hospital authorities must be obtained, and that the deputation must be prepared to guarantee the College a sufficient amount to cover the fees in those cases in which the Professors declined to lecture to double classes.

Dr. Richardson's success as a popular lecturer is so well known that one was not surprised at the large audience that assembled to hear his lecture on "Tobacco in relation to Health." The Midland Institute have wisely secured his services, as well as those of Dr. Ferrier, for lectures on physiological subjects during the ensuing session.

The medical profession in Birmingham have to deplore the death of Dr. Alexander Fleming, late Physician to the Queen's Hospital, at the comparatively early age of fifty-one. He had been in practice here about eighteen years, and during that time had acquired a high and well-deserved reputation as an exact and careful physician, and as a therapeutist of great skill. His kindliness and patience as a clinical teacher made him respected and beloved by all pupils, and his courtesy and ability secured for him the esteem and regard of a large circle of professional as well as private friends. Dr. Fleming died from chronic renal disease. Death has also been busy among the younger members of our body. Mr. E. B. Ravenhill, late house-surgeon to the General Hospital, Wolverhampton, died suddenly at the age of twenty-five, from syncope, after a few days' suffering, with symptoms of gastro-intestinal catarrh, the effect in all probability of overwork. Mr. J. T. Smith, of Sutton Coldfield, has also died quite suddenly, while in the full vigour of manhood. He had been, like Mr. Ravenhill, a distinguished student of Queen's College, and he had subsequently held the appointments of house-surgeon to the Lying-in Hospital and resident medical officer at the Birmingham Dispensary.

The Medical Institute is said to be making good progress. Two hundred volumes have already been presented, and a "local habitation" is about to be secured to give room for further gifts and purchases.

The necessary arrangements are being made for Hospital Sunday. The appeal from the pulpits will be made on Oct. 31st, and will be on behalf of the Queen's Hospital.

Diarrhœa is very prevalent, but in other respects the town is healthier than usual at this season of the year.

Birmingham, Sept. 20th, 1875.

NEWCASTLE-ON-TYNE.

(*From our own Correspondent.*)

WE boast of a Vegetarian Society here, and the other night it gave a grand banquet in furtherance of its principles. It was very numerously attended by ladies and gentlemen. The *menu* was as follows:—Vegetarian pie, vegetable marrow stuffed with fried potatoes, potatoes roasted, potatoes mashed, haricot beans and parsley sauce, English beans, English peas, tomatoes, onions boiled, onions roasted, boiled lentils, plain pudding, rice pudding, sago pudding, mixture of apples and preserved stewed apples, and stewed pears. Numerous enthusiasts in the vegetarian's *régime* were constantly explaining the qualities of the various dishes. The majority of the guests seemed undoubtedly to enjoy the banquet, but to many a sigh of relief involuntary came when the cooked dishes were removed and the *dessert* fruit was placed upon the table. A public meeting was afterwards held to promote vegetarian views, and the company separated on the whole well pleased with their harmless experiment.

The ancient and picturesque little town of Chester-le-street, with its historical castle at Lumley and interesting church so rich in sculptured monuments of knights and crusaders, used to be a favourite drive from Newcastle and Gateshead, and its neighbouring slopes attractive resorts for pic-nic and other excursion parties; but latterly the good old town has literally fallen into "bad odour" with all health and pleasure seekers, and travellers for some time past have been fain to give it the "go by," and endeavour to reach their destination by circuitous routes rather than cross its bridge and encounter the smells from its "burn," as the open sewer partly surrounding the town is called. Time was, no doubt, when the Chester Burn was a crystal stream and purling tributary of the Wean, but of late it has become a drain of the foulest character, poisoning the neighbourhood with its nauseous emanations. There have, of course, been meetings called for "the purpose of considering the state of the Chester Burn." "Sanitary meetings," "township meetings," "guardian meetings," inspections, committees, estimates, discussions, propositions, amendments, postponements; but still the stench increases. There has been no amendment in the nuisance; nothing has been really done, notwithstanding all that has been said to remove a plague which bids fair to blight one of our most quaint, interesting, and beautiful of northern towns.

Newcastle-on-Tyne, September 8th, 1875.

IRELAND.

(*From our own Correspondent.*)

Some time since a skating-rink was opened at Kingstown, which has been productive of not a few accidents, sufficiently important to require surgical treatment. Fractures of the radius and sprains and dislocations of the arm and wrist have in some instances resulted from this novel, so-called, skating. On the 6th inst., Mr. John Burr Maguire, a young gentleman only nineteen years of age, fell on the rink and died suddenly of heart disease.

The loss of the ironclad line-of-battle ship *Vanguard* continues to attract much of public attention here. Daily efforts are being made, with considerable success, by Captain Batt, of Devonport Dockyard, and the divers, riggers, and crew of the *Carron* steam-tug, in the recovery of rigging, &c., of the submerged ship. In a medical point, the process of diving at so considerable a depth is a matter of much interest; the present extremely fine weather is most fortunate for the work.

An unfortunate female, Anne Byrne or Burden, has just died at Steevens's Hospital of injuries sustained by falling from or being shoved out of a window, as she asserted, at the Royal Barracks in this city. Evidence has been forthcoming to show the fearfully degraded state of the wretched women inhabiting the houses in the locality to which Anne Byrne or Burden belonged, and which has been long since condemned by the medical officers of that district of the city as unfit for habitation. I believe that a recommendation has been made by the Dublin Sanitary Association that the place in question, Skinner's-alley, should be pulled down, and that the houses comprising it are all of the number condemned long since by the Dublin Corporation as unfit for human habitation. I trust, moreover, that an investigation will be undertaken as to the condition of localities occupied by the class of unfortunates in some of the worst localities in Dublin, and that the inquiry will embrace the very important question of the propriety of extending to this city the Contagious Diseases Prevention Act. Such places are too frequently a snare for young soldiers and other strangers in Dublin, and parties of military are not uncommonly to be seen on duty in such localities, endeavouring to find missing men.

Statements as to the condition and unsuitable position of certain slaughterhouses in Dublin having been made to the Dublin Sanitary Association by owners of property adjoining some of these places, complaining of injury arising therefrom to the public health and to property, the Association asked the local authority for a list of the licensed slaughterhouses, which was at first evaded, and, lastly, refused so discourteously as to draw forth comments from all the leading local journals reflecting severely upon such conduct.

The citizens who have at heart the interests of the working classes, and therefore of the whole community, bound up together as we are by so many ties, not apparent, as it may be, to casual observers, have been much surprised to learn that "the visiting committee" of the South Dublin Union approve the interment of 500 more bodies in a small tract of ground near St. Patrick's Cathedral long used as a burial-ground. I may observe that this place is close to the Meath Hospital and County Dublin Infirmary, is surrounded by overcrowded tenements, from which fever, exanthemata, or other illnesses, are never absent, and it was this neighbourhood that served as a centre for the spread of the worst form of small-pox and of cholera in recent epidemics; indeed, if space permitted, very many other reasons, as the coexistence of manure yards, schools for the poor, dairy yards, &c., in and around this spot, could be given, to show the injudiciousness of the recommendation in question.

The first meeting of the Council of the Pharmaceutical Society of Ireland took place at the College of Physicians on the 10th inst. The proceedings were announced as private, no reporter being present, and were, as I am informed, merely of a preliminary nature. The Council was adjourned, the next meeting to take place on or about the 22nd inst.

Captain Webb's swimming feat has induced others to attempt performances in the same line, which, though on a far more humble scale as to distance, resulted fatally in one case—that of a man who attempted to swim across one of the lakes in the centre of Ireland. Bathers in fresh water should bear in mind that, in addition to the diminished buoyancy of their bodies in water of a less specific gravity than salt water, there is also a greater frequency of coldness in parts of lakes, &c., from springs, which has often been attended with fatal consequences to bathers. In such water, too, there is wanting the peculiar stimulating effect of salt water, which doubtless favours the swimmer in sea water.

Dublin, Sept. 14th, 1875.

Medical News.

Apothecaries' Hall. — The following gentlemen passed their examination in the Science and Practice of Medicine and received certificates to practise on Sept. 16th:—

Archer, Robert Kendray, Cathcart-hill, Highgate.
Dearden, John Alfred, Douglas, Isle of Man.
Todd, John, Union-road, Tufnell-park.

The following gentlemen passed the Primary Professional Examination on the same day:—

William John Cant and Alfred Pratt, Queen's College, Birmingham.

The late Dr. Alexander Fleming.—The following resolution, carried unanimously by the Medical Committee of the Queen's Hospital, Birmingham, shows the high estimation in which that gentleman was held by his colleagues:—"The members of the Medical Committee desire to express their deepest sympathy with Mrs. Fleming in her great bereavement. In the death of Dr. Fleming they have been deprived of a most esteemed colleague, and the Queen's Hospital has lost a valued consulting officer."

Suicide of a Medical Gentleman.—A very distressing suicide is announced as having occurred in the West Riding. Dr. Tatham was in the company of his sister in his orchard at Burton in Lonsdale on Saturday evening, and while left alone for a few minutes he cut his throat. On being found in this condition shortly afterwards, he was conveyed into his house close by. Medical assistance was at once obtained, and the wounds were sewn up. The deceased, though sensible, never rallied, and died about two hours afterwards. Dr. Tatham had been suffering from general ill-health for some time, but beyond this there is nothing to account for the act.

Mortuaries.—At a meeting of the Strand Board of Works, on Wednesday, September 22nd, the following motion, by Dr. Joseph Rogers, was carried unanimously:—"That with the view to the more effectually and economically securing the establishment of mortuaries in the metropolis, this board do memorialise the Metropolitan Board of Works to apply in the next session of Parliament for powers authorising that body to undertake their erection in such parts of the metropolis as may be considered necessary." It was also resolved that a copy of the resolution should be forwarded to the several boards of works in the metropolis, and that they should be requested to co-operate with the Strand Board in pressing the question on the attention of the Metropolitan Board. Dr. Joseph Rogers, Mr. Betts, Mr. Phillips (the representative of the board on the Metropolitan Board), and Mr. Jenkins, the clerk, were appointed to draw up the form of memorial to be forwarded to the Metropolitan Board.

Vaccination Certificates by Unqualified Practitioners.—At the Chester-le-street Petty Sessions Mr. Percival Hall, of Holmside, was charged under the 40th section of the Medical Act, 1858, with having signed a vaccination certificate, he having no qualification entitling him to give such certificate. No attempt was made to dispute the facts, but on behalf of the defendant it was contended that the case did not come within the Act. The magistrate, after consultation, inflicted a fine of £10 and costs, but, on the application of the defendant's solicitor, granted a case for a superior court.

Medical Appointments.

Adams, R. S., M.R.C.S.E., has been appointed Medical Officer and Public Vaccinator for the Lymington District of the Lymington Union.

Addy, B., M.D., M.R.C.S.E., has been appointed a Medical Officer to the new Branch of the Salford and Pendleton Royal Hospital and Dispensary, Manchester.

Brook, C., M.R.C.S.E., has been appointed an Hon. Surgeon to the Lincoln General Dispensary, vice Snow, deceased.

Brookfield, J. S., M.D., M.R.C.S.E., has been appointed Medical Officer for the Emley and Flockton Districts of the Wakefield Union.

Calthrop, E., L.R.C.P.L., M.R.C.S.E., has been appointed Surgeon to the St. Saviour's Hospital and Refuge for Women and Children, Upper Holloway, vice Lucey, appointed Resident Physician to the Ben Rhydding Hydropathic Establishment.

Cobban, A. R., M.B., C.M., hitherto Medical Officer of Health for the Kimberworth Sub-district of the Rotherham Rural Sanitary District, has now been appointed to the whole district.

Crawford, W., M.B., C.M., has been appointed House-Surgeon to the Blackburn and East Lancashire Infirmary, vice Stewart, resigned.

Eaton, J., L.R.C.S.I., has been appointed Medical Officer and Public Vaccinator for the Parishes of Sandsting and Walls, Shetland, vice Pole, resigned.

Elder, G., M.B., C.M., has been appointed Surgeon to the New Hospital for Women, Nottingham.

Elliston, G. S., M.R.C.S.E., has been appointed Certifying Factory Surgeon for Ipswich, vice Adams, resigned.

Fay, T., M.R.C.S.E., has been appointed an additional Hon. Dental Surgeon to the Liverpool Dental Hospital.

Fiske, J. F., M.R.C.S.E., has been appointed Medical Officer and Public Vaccinator for the Donhead District of the Tisbury Union, vice Thompson, resigned.

Freer, J. H., L.R.C.P.L., M.R.C.S.E., has been appointed Medical Officer and Public Vaccinator for the Rugeley District of the Lichfield Union, vice Tibbits, resigned.

Greenwood, J. W., M.R.C.S.E., L.M., has been appointed Medical Officer for the Shitlington District of the Wakefield Union.

Harrison, C., M.D., has been appointed Hon. Physician to the Lincoln General Dispensary.

Hesslegrave, J., M.R.C.S.E., has been reappointed Medical Officer of Health for the Golcar, Linthwaite, Longwood, Marsden-in-Almondbury, Marsden-in-Huddersfield, Scammonden, and Slaithwaite Urban Sanitary Districts.

Heaps, J., L.R.C.P.Ed., L.M., M.R.C.S.E., has been appointed Medical Officer for the Lofthouse-with-Carlton and Thorpe Districts of the Wakefield Union.

Hirst, C., L.R.C.P.Ed., has been appointed Medical Officer for the Ardsley West District of the Wakefield Union.

Horsfall, H., M.R.C.S.E., has been appointed Medical Officer for the Crofton District of the Wakefield Union.

Jameson, T., M.D., L.R.C.S.Ed., has been appointed Assistant Visiting Surgeon at Plymouth, Devonport, Dartmouth, Ivy Bridge, and Plympton, under the provisions of the Contagious Diseases Acts (Women), vice Archer, appointed Visiting Surgeon.

Kemp, B., M.R.C.S.E., has been appointed Medical Officer for the Ardsley East District of the Wakefield Union.

Lorraine, W. J., L.R.C.P.Ed., L.M., M.R.C.S.E., has been appointed Medical Officer for the Chevet, Sandal-Magna, and Walton Districts of the Wakefield Union.

Loudon, J., M.D., has been appointed Medical Officer to the Combination Poorhouse, Hamilton, Lanarkshire, vice Naismith, deceased.

Lucas, R., M.D., C.M., has been appointed Certifying Factory Surgeon for Dalkeith, vice Jefferiss, deceased.

M'Kechnie, A., M.B., C.M., L.R.C.S.Ed., has been appointed Assistant Medical Officer to the Inverness District Lunatic Asylum, vice Weir, whose appointment has expired.

Mackenzie, W. S., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer for the Sharlston District of the Wakefield Union.

Madeley, G. S., M.R.C.S.E., has been appointed Surgeon to the Hospital for Incurables, Ardwick-green, Manchester.

Marshall, J. S., M.D., C.M., has been appointed Medical Officer and Public Vaccinator for the Parish of Hamilton, Lanarkshire, vice Naismith, deceased.

Newman, W. J., M.O.S. Gt. Brit., the founder of the Liverpool Dental Hospital, has been appointed a Consulting Dental Surgeon.

North, S. W., M.R.C.S.E., L.M., has been appointed President of the newly formed Association of Medical Officers of Health of Yorkshire.

O'Keefe, M., M.D., has been appointed second Examiner in Medical Jurisprudence at the Queen's University in Ireland.

Orchard, T. N., M.D., C.M., has been appointed a Medical Officer to the new Branch of the Salford and Pendleton Royal Hospital and Dispensary, Manchester.

Pasley, A. C. B., L.R.C.P.L., L.R.C.S.I., has been appointed Resident Medical Officer to the Dover Hospital and Dispensary, vice Webb, resigned

Phillips, E. J. M., M.R.C.S.E., L.D.S., has been appointed an additional Hon. Dental Surgeon to the Liverpool Dental Hospital.

Smailes, T., M.R.C.S E., has been appointed Medical Officer to the County Constabulary, and to the Odd Fellows', Druids', and Gardeners' Friendly Societies, Honley, Yorkshire, vice Todd, deceased.

Smith, R. D., M.R.C.S.E., has been appointed Resident Medical Officer to the London Hospital, vice Lewis Mackenzie, L.R.C.P.L., resigned.

Stewart, R. E., L.D.S. R.C.S.E., Senior Dental Surgeon to the Liverpool Dental Hospital, has been appointed a Consulting Dental Surgeon.

Thomas, E. F., L.R.C.P.Ed., M.R.C.S.E., has been appointed Medical Officer and Public Vaccinator for the Shepperton District of the Staines Union, vice Jones, resigned.

Wesley, J. S., M.B., M.R.C.S.E., has been appointed Secretary and Treasurer of the newly formed Association of Medical Officers of Health of Yorkshire.

Wilkinson, T. M., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed a Medical Officer to the Lincoln General Dispensary, vice Lowe, resigned.

Wise, T., L.R.C.P.L., M.R.C.S.E., has been appointed Medical Officer and Public Vaccinator for the No. 2 District of the Northleach Union, and Medical Officer of Health for the No. 2 Sub-district of the Northleach Rural Sanitary District, vice Swan, resigned.

Births, Marriages, and Deaths.

BIRTHS.

Bryant.—On the 10th inst., at Sussex-square, the wife of John H. Bryant, L.R.C.P.Ed., of a son.

Farr.—On the 17th inst., at Slade House, Kennington-road, the wife of Geo. F. Farr, L.R.C.P.Ed., of a son.

Hoffman.—On the 17th inst., at Fulham, the wife of H. W. Hoffman, M.B., of a son.

Noad.—On the 18th inst., at East Cowes Villa, Lower Norwood, the wife of H. C. Noad, L.R.C.P.L., of a son.

Oliver.—On the 18th inst., at West-end-park, Harrogate, the wife of Geo. Oliver, M.D., of a daughter.

MARRIAGES.

Blythman—Ellis.—On the 16th inst., at Thurnscoe, Clement S. Blythman, M.B., of Swinton, to Annie, only daughter of J. D. Ellis, Esq., of Thurnscoe Hall, Yorkshire.—No Cards.

Hill—Nelson.—On the 9th inst., at Sparham, Norfolk, T. Wood Hill, L.R.C.P., M.R.C.S., L.S.A., of West Cromwell-road, South Kensington, to Mary, daughter of the late Thomas Nelson, Esq., of Sparham.—No Cards.

Dyer—Barton.—On the 15th inst., at St. James's Church, Sutton, Macclesfield, Cheshire, Henry Gearey Dyer, M.R.C.S.E., L.R.C.P.Ed., of Ringwood, Hampshire, to Annie Louise, youngest daughter of the late Samuel Barton, Esq., of Parvey, Sutton.

M'Dowall—Carey.—On the 21st inst., at the Parish Church, Ryton-on-Tyne, Dr. T. W. M'Dowall, Northumberland County Asylum, Morpeth, to Alice, eldest daughter of H. C. Carey, Esq., of Elsinore, Denmark.—No Cards.

Maclaren—Campbell.—On the 15th inst., at St. Paul's Church, Carlisle, Roderick Maclaren, M.D., to Isabella Emma, youngest daughter of the late Rev. Duncan Campbell, of North Knapdale.

DEATHS.

Bower.—On the 7th inst., at Wilmslow, Cheshire, Joshua Bower, M.R.C.S.E., aged 44.

Clarke.—On the 5th inst., at Trincomalee, Wm. H. Clarke, M.R.C.S.E., Staff Surgeon R.N., aged 52.

Cooper.—On the 17th inst., at Woburn-place, Geo. L. Cooper, F.R.C.S.E., aged 65.

Dempsey.—On the 14th inst., at Charterhouse-square, Joseph M. Dempsey, M.D.

Gell.—On the 10th inst., at Southam, Warwickshire, Isabella Sarah, wife of Alfred Scott Gell, M.R.C.S.E., aged 38.

Hirst.—On the 16th inst., at Morley, Yorkshire, Lionel Hirst, M.R.C.S.E., aged 32.

Pope.—On the 16th inst., at Scarsdale Villas, Kensington, Catharine Eliza, wife of Edward Pope, M.R.C.S.E., L.M., of Tring, Herts, and mother of H. Campbell Pope, M.B., B.S., Queen's College, Birmingham.

Richardson.—On the 18th inst., at Oatlands, Mortimer-road, Kilburn, Wm. Richardson, M.D., aged 64.

Smith.—On the 12th inst., J. T. Smith, M.R.C.S.E., of Sutton-Coldfield, Warwickshire, aged 39.

[N.B.—*A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*]

Notes, Short Comments, and Answers to Correspondents.

A Rare Wine.

At a banquet given lately by the Board of Irish Lights to the officers of the Reserve Squadron of the Channel Fleet at Kingstown, among various dainties provided for the guests was some port wine which was on board Lord Nelson's ship, the *Victory*, at the battle of Trafalgar. That port wine or indeed any wine at that age could be worth drinking is a matter of opinion; but even the most inveterate temperance advocate might safely enjoy a beverage of the kind, as only the merest trace of alcohol would be likely to be present.

F. E. H. I.—Speaking generally, a marriage of such near consanguinity would be decidedly unadvisable. There may, however, be exceptioal circumstances, such as the most perfect health on each side, which would minimise any mischief likely to ensue.

Mr. J. V. Solomon, (Birmingham.)—We do not publish communications that have appeared elsewhere.

Practical Hints for the Sick-room.

Notwithstanding the way in which the training of nurses for the sick and the like has been discussed of late years, the subject still affords opportunity for an intelligent and shrewd observer to say something worth reading. *Chambers's Journal* for the 11th inst. has a short article, headed "Practical Hints for the Sick-room," in which the subject is touched with a light hand—presumably a lady's hand,—but with acuteness and good sense. To make a really good nurse requires suitable qualities of character and temperament; but whether a woman possesses these or not, she is pretty sure to have to discharge at some time or other the duties of a nurse, and it is something in her favour if she knows how to avoid being a worry to her patient and everybody else, instead of a help. Thoughtfulness is one thing, fussiness another, and there are a few practical points and considerations in the article to which we are referring which a lady will be none the worse for appreciating. We agree with the writer in protesting against the common practice of the amateur sick nurse making a "guy" of herself; but we think that a print dress is, on the whole, the best. There is much truth in the remarks on that over-zealous, excitable variety of nurse, who insists that she can keep up, but is always hinting, nevertheless, that she must inevitably break down in time—a kind of self-sacrifice that is always acting as its own bill-poster.

Mr. Jeaffreson, (Newcastle.)—It shall be kept in mind.

Poisoning by Six Grains of Strychnia; Recovery.

To the Editor of The Lancet.

Sir,—I was called on August 31st to see Miss ——. When I arrived my friend Mr. Cambridge (who was in charge of the case) informed me that a poisonous dose of strychnia had been taken in the form of vermin-killer. At about 3.30 p.m., after a good dinner, it had been swallowed. About 4.30 p.m. it was discovered by her friends, who, not knowing what she had taken, commenced to walk her quickly up and down a passage till the tetanic spasm became so severe that she was no longer able to walk. About 5 p.m. she was found by us lying upon the couch in her bedroom, her face ghastly pallid, covered with perspiration, wearing an expression of fearful mental agony, in the apprehension of death. She was thrown into violent clonic spasm by sound or movement, even of a slight nature, especially if that sound or movement were sharp. The spasm, too, was general, and when the seizure was at its height there was well-marked opisthotonos and fearful muscular pain, with great diminution of respiratory movement. Mr. Cambridge, I found, had already administered one scruple of sulphate of zinc. This quickly acted. The first vomit was of a bluish colour. We then supplied her with warm drink, encouraging her thus to continue vomiting. I hoped to empty the upper part of the small intestine. When the emetic action had ceased, we administered tincture of conium, one drachm; tincture of belladonna, forty minims; water, one ounce. The belladonna was then continued in ten-minim doses every quarter of an hour till one drachm ten minims had been given. The expression was now less horror-struck, the pupils were dilating, and spasms less marked, but still severe. Doubting the propriety of giving any more belladonna, I immediately commenced the inhalation of chloroform. To my great satisfaction the fits grew less and less marked, till after two hours' administration they had almost entirely ceased. Her reflex functions were, however, greatly exalted. For hours, if the bedstead were touched suddenly, there was more or less spasm. She is now well.

I find upon inquiry at the chemist's who sold the vermin-killer that she took "six grains" of *strychnia!* and *this amount can be purchased by any adult of respectable appearance who gives a satisfactory reason for the purchase!* Now, is the sale of poisons to be restricted? How is it possible to carry out the measures for this end if poisonous doses of strychnia can be bought for a few pence under another name?

I remain, Sir, yours truly,
C. Lammiman, L.R.C.P.L., &c.,
September, 1875. House-Surgeon, Tunbridge Wells Hospital.

Medical Officer.—The unpopularity is due, among other things, as Dr. Lush pointed out in the House of Commons, to the state of uncertainty as regards everything connected with the position of the medical officers, consequent upon the frequent issuing of warrants, and the cancelling of the provisions of some immediately afterwards by circulars; taking away from the medical officer to-day what was given to him yesterday. Mr. Hardy has done nothing yet to relieve the existing tension, and medical officers must for the present be content to remain in a state of expectant attention.

Insurance against Sickness.

To the Editor of The Lancet.

Sir,—Seeing the letter of "Nemo" in your impression of Sept. 4th in reference to having a Sick Club in connexion with the profession, I am sorry to say there is no such Society in existence. It would, however, be very easy to get up one, and it could be registered under the new Friendly Societies Act without any expense whatever. I would propose to form a Society, age of admission from twenty-five to fifty, allowing £1 10s. per week in illness or accident, with £30 at death; £2 per week and £40 at death; £4 per week and £60 at death; half benefit in six months, full benefit in twelve months, after joining the Society. The sick pay to continue for twenty-six weeks; half pay for twenty-six weeks longer; after that to be reduced to quarter benefit. Having been connected with large Industrial Insurance Companies for some years, I shall be most happy to draw up tables for the formation of a Sick Fund in connexion with the profession; and if "Nemo" and any other gentlemen will join in the establishing such a Society, I shall be glad to have their names and addresses in next Saturday's Lancet. Yours very truly,
September 6th, 1875. L.S.A.

P.S.—It would require a Committee of at least twelve members to meet once a week, having a chief office in London. All premiums should be paid quarterly in advance.

Infected Linen.

Dr. Sedgwick Saunders, in a recently issued report on the Sanitary Condition of the City, states that a striking illustration of the mode in which disease might be spread by washing infected linen had arisen within the last few days, and it might serve as a warning to mention the following details. Two children of a City policeman hed passed successfully through an attack of scarlet fever, and upon their recovery the clothes and bedding they had used were sent to the laundress to be washed. That woman had two children, who at the time she received the articles were in perfect health. Shortly afterwards both were seized with scarlet fever, and passed through its various stages, happily without fatal results. In view of the serious consequences which might and often did accrue from the too frequently culpable indifference shown in mixing the clothing and bedding of infected persons with those of the healthy, he had taken some pains to investigate the facts of the case in order to ascertain how far there had been any infraction of the law, which directs certain penalties against any person who should by negligence or want of reasonable precaution favour the spread of infectious diseases; and having ascertained that the father of the children first attacked gave notice to the laundress of the circumstances attending their illness, he did not recommend any further steps to be taken in the matter.

Mr. Thoms is thanked for his courteous communication.

An Appeal.

To the Editor of The Lancet.

Sir,—May I ask you to find room in your columns for the following sad case:—

W. H. Goodchild was for many years dispenser to the Metropolitan Dispensary, where he earned the esteem of the staff and the affection of the patients. He had entered as a student at St. Bartholomew's Hospital, and, in spite of the many other calls on his time, he had, in April last, passed the primary professional examination of the College of Surgeons. On Saturday, Sept. 4th, after finishing his dispensing, he complained of lassitude and sore-throat; the next morning the rash of scarlatina appeared, and on Wednesday he sank, the poison of the disease being too much for a body borne down by overwork. The most lamentable feature of the case is that he leaves a widow and three children (with an addition expected) to subsist on the produce of a small life policy. In the hope that some of your readers may be induced to come to the assistance of the family so suddenly reduced from comparative comfort to the verge of want, I have ventured to trespass on your space.

Subscriptions will be most thankfully received by the Manager of the London and County Bank, Aldersgate-street Branch; by Dr. Southwood at the Metropolitan Dispensary, Fore-street; and by,

Your obedient servant,
F. de Havilland Hall.
6, Bedford-place, Russell-square, Sept. 11th, 1875.

⁂ The case brought under the notice of the profession by Dr. Hall is a sad one, and will we hope evoke the sympathy and practical support of those members who, in affluent circumstances themselves, have little conception how sorely the battle of life presses on their less fortunate brethren, or of the privations and distress frequently endured by their bereaved families. Our columns are never closed to appeals of this nature, and we are pained that the necessity for making such appeals arises so frequently.—Ed. L.

M.D.—An establishment employing six girls is distinctly under the Workshops Act, and subject to inspection by the Factory Acts staff. The particulars should be forwarded to the Chief Clerk, Factory Inspector's Office, New Home Office buildings, Whitehall, who will furnish all necessary information.

The Penetrating Power of Salt.

To the Editor of The Lancet.

Sir,—A strong solution of salt and water was left standing all night in a ware jug, *glazed both inside and out,* and in the morning the outside of the jug was found to be thickly covered with crystals of common salt. The experiment was repeated the next night, great care being taken to dry the outside of the vessel, and in the morning the crystals were again found on the outside of the jug over a surface exactly corresponding with the amount of water in the jug. It shows the great power of penetration which is possessed by salt, and consequently I think it must be considered of great value as a local remedy in cases of gout, rheumatism, &c.

I am, Sir, yours truly,
September, 1875. A. B.

A Constant Reader.—It is usual to make charges in such cases, although we are aware many practitioners, actuated by motives of generosity, never think of sending in a bill for attendance and medicines, except under special circumstances.

F. E. P. H. should consult a medical practitioner.

The Treatment of Tumours of the Lymphatic Glands.

To the Editor of The Lancet.

Sir,—I have received a letter from Mr. Coates, Surgeon to the Salisbury Infirmary, stating that he has for many years employed iodine subcutaneously in treating enlarged glands and various other tumours, and refers me to a paper in the *Medical Times and Gazette* for Nov. 2nd, 1867, in confirmation of this statement. I much regret that I was not aware of Mr. Coates's priority in this matter, as I find I have unintentionally taken credit to myself for what he had in almost every particular described eight years ago, and I write now in the hope that I may be able to undo the wrong I have done him in claiming this plan of treatment as a discovery of my own.

I am, Sir, yours &c.,
Manchester, Sept. 14th, 1875. S. Messenger Bradley.

Quacks in Liverpool.

Our contemporary the *Globe* shows that Liverpool is especially infested by quack doctors. An auctioneer's services were recently called for by a cobbler who had agreed to purchase the business and stock-in-trade of a certain quack. For the goodwill £300 was charged, but the drugs had to be taken over at a valuation. On inspecting these, the auctioneer found them to consist of about 500 pills made of Windsor soap, coated with silver, and some bundles of dried parsley and mint. In addition to these valuable goods, a number of foreign diplomas were to go with the business, although the outgoing "doctor" could neither read nor write. Another correspondent describes the *modus operandi* by which some of these unscrupulous cheats manage to pluck their victims. A patient waits upon one of the fraternity, and describes his symptoms. The quack shakes his head, and assumes a very serious look. "Yours is a very bad case, very bad indeed," he says, fingering away at his visitor's pulse; "I cannot take upon myself to treat it without professional assistance." Of course, the victim, terrified by this alarming diagnosis, at once consents to have a regular physician called in, who in due time makes his appearance, consults with the quack, pockets a guinea fee, and takes his departure. It is needless to say that this eminent authority is no more a physician than the quack is a doctor, the two being equally ignorant of medical matters. In one case the physician was even discovered to be the barman at a neighbouring pothouse, who, on receiving notice from his accomplice, would slip off his white apron, don a black coat, and assume a solemn air, preparatory to consulting with his learned friend. In another instance a quack, who has advertised himself for years as "Dr.," and who has "M.D." painted after his name on the door of his house, possesses only the most elementary education, being barely able to spell words in one and two syllables.

Dr. Corfield.—The arrangement proposed will do very well.

Fever in Hurdsfield.

To the Editor of The Lancet.

Sir,—In your impression of last Saturday, in correcting a clerical error, you state that the Vicar of Hurdsfield (Macclesfield) refused to close his schools at the demand of Mr. George Bland, medical officer of health, during an outbreak of scarlet fever, but you make no mention of any reason on his part for so acting.

I think it only right, therefore, to explain that Mr. Handcock, the Vicar, was only acting on the advice of a large majority of the medical men of the town, who signed a memorial to the effect that they considered the children far more safe from infection in the clean, well-ventilated, and well-drained Hurdsfield schools than in the dirty, insanitary state of their own homes. That the schools were in a proper state was proved by the detailed report of the sanitary inspector, who investigated into the matter, and who certified that there was no defect whatever in the drainage of the place, and that it was clean and well ventilated. I may add that the memorial before mentioned was signed (with the exception of Mr. G. Bland and his father, Mr. J. Bland) by the whole of the staff of the Macclesfield Infirmary.

Having while on a visit to Mr. Handcock been over the schools in question, I can most thoroughly endorse the fact of their thorough cleanliness and ventilation, and feel sure that one visit would be enough to convince anyone (both by sight and smell) of the filthy and unhealthy condition of a great number of the houses in the parish. That the epidemic ever did really originate or increase through the schools, no satisfactory proof was ever brought, and no one who knew the facts of the case thoroughly could ever assert truthfully that Mr. Handcock ever did, or could, want to obstruct the medical officer in his work.

I am, Sir, yours faithfully,
Leighton Kesteven.
Verulam Club, St. James's-street, S.W., Sept. 20th, 1875.

Population in Europe.

The *Revue Scientifique* states that in Europe there is an increase of population in every State; but this augmentation is not constant, and decreases gradually. Thus, in France, during the ten years comprised between 1821 and 1831 it was 0·69 per cent.; from 1831 to 1841 it fell to 0·50 per cent.; from 1841 to 1851 to 0·46 per cent.; and from 1851 to 1861 to 0·26 per cent. In England for the same period, the figures were respectively 1·46, 1·35, 1·19, and 1·20 per cent. In Prussia, from 1817 to 1828, it amounted to 1·71 per cent.; from 1828 to 1840 to 1·35; from 1840 to 1846 to 1·27; and from 1846 to 1864 to 1·09 per cent. In the following table, compiled by M. Maurice Block, the present annual increase in each country is given, together with the number of years in which the population would be doubled if the same ratio continued:—

Countries.	Annual increase per cent.	Years.
Russia	1·39	50
Scotland	1·31	53
Sweden and Norway	1·30	53½
England	1·29	54
Prussia	1·13	61½
Saxony	1·10	63
Denmark	1·09	64
Wurtemburg	1·04	67
Spain	0·89	78
Italy	0·70	99
Ireland	0·59	118
France	0·35	198

Inquirer.—Lord Blachford's article on Prof. Huxley's hypothesis that animals are automata will be found in the *Contemporary Review* for the present month.

Mr. Osborn Walker.—Certainly not. It would be illegal.

Medical Extras.

The guardians of St. Pancras are chafing at the great increase of expenditure incurred by the consumption of "medical extras" in the St. Pancras Workhouse. The following is described as the average dietary allowance for one week of an inmate receiving these extras, which, we confess, is by no means illiberal—viz., 5½ lb. of bread, 3½ lb. of eels, 3½ lb. of meat, 14 eggs, 14 pints of tea, 3½ lb. of rice pudding, 8 oz. of butter, 7 pints of milk, 3½ pints of porter, 14 oz. of arrowroot, 14 oz. of sugar, 42 oz. of whisky, and 14 lemons. It is added that sometimes the diet varied, the eels being substituted by soles or poultry. To buy all these things, it was stated, in the ordinary way would cost 20*s.* per week, but even at the contract prices they cost over 15*s.* It was asserted that the "medical extras" reached during the year £2064; that the consumption of brandy had increased from £143 in 1871 to £451 in 1875; that the expenditure in gin had increased by 140 per cent.; and that whisky, an item never previously known, had cost £117. Fish had increased from £15 to £127; and the speciality of eels, not known before, had cost £14. As the medical officer, Dr. Hill, held out no hope of any reduction, arguing that the increase of extras was owing to the changed character of the cases in the house, the committee of guardians feel they have no power in the matter. A motion to send the whole matter to the Local Government Board has been carried.

Hope, (India.)—We do not think it advisable to notice the subject. Our doing so would only give it a prominence which it does not merit.

Meningitis and Orchitis after Mumps.

To the Editor of The Lancet.

Sir,—The following case may be considered of sufficient interest to have a place in your columns.

Mr. B—— is a muscular, active man, aged twenty-eight. His uncle when twenty-two years old had mumps, which went to the testicles and brain; three adult sisters and one brother (aged nineteen) have had this disease; in the brother's case orchitis followed. No discoverable source of infection. On the 10th July, after an exhausting day, he sat out the evening, and slept in his wet clothes. On the next day he fainted in church; sickness; hepatic tenderness; tongue furred; headache.

July 12th.—Feels better; deglutition difficult and painful from stiffness.

13th.—Well-marked swelling of both parotids.

17th.—Swelling of parotids has disappeared; left testicle tender.

18th.—Well-marked orchitis of left testicle.

19th.—Face flushed; expression of great pain; nausea; tongue dry, yellow, and glazed; bowels confined; skin dry; shooting pains across forehead and at back of eyes, muscæ, flashes; delirium; no sleep; feels as though a great weight were pressing on his head; general hyperæsthesia; does not complain of testicle, which seems in the same condition. Temperature 103·6°; pulse 96, small and hard.

20th.—Morning temperature, 102·9°; pulse 96. Evening temperature, 103°; pulse 96. No sleep; pain general over head; any movement increases it; cannot bear the light; testicle tender, but not painful; sweats profusely; complains of nose feeling hot.

21st.—Morning temperature, 101·7°; pulse 72; respiration 21. Evening temperature, 102°; pulse 78; respiration 20.

22nd.—Morning temperature, 99°; pulse 84. Evening temperature, 98·5°; pulse 54. Epistaxis; profuse sweating; sudamina; pain in head gone.

23rd.—Pulse 52.

25th.—Pulse 48. After this the pulse gradually rose in frequency.

Aug. 2nd.—A servant in the house has mumps.

I remain, Sir, yours truly,
September, 1875. M. S. Duke.

Dr. Berridge, (Highbury.)—We have failed to discover any Transactions of the Royal Medico-Botanical Society of London, and we suspect that the only record of its proceedings extant is that to which our correspondent refers—viz., in the pages of the *London Medical and Surgical Journal*, which was edited by John Foote, who was also one of the Secretaries of the Society. In his "Autobiographical Recollections" the late Mr. Clarke has devoted a chapter to the history of the rise and fall of this curious Society, which only existed during the tenure of office of its first President, Lord Stanhope. Perhaps some of our readers who were members of it may be enabled to inform our correspondent whether any Transactions or MSS. of the Society are in existence.

Z. Y.—Certainly.

Dr. W. Alexander's paper on "Progressive Muscular Atrophy," &c., has been received, and will shortly be published.

An Idea.

To the Editor of The Lancet.

Sir,—Immediately I heard of Mr. Darwin's experiments with insectivorous plants, it occurred to me that the principle or principles in virtue of which these plants dissolve albuminous substances might possibly be found useful, as pepsine is, in assisting the digestive powers of the human stomach. This idea must have occurred to many others as well as to myself. But have any steps yet been taken with the view of ascertaining whether it can be turned to any practical account? Your obedient servant,
Sydenham Hill, Sept. 5th, 1875. F. Chance.

Mr. W. B. Holdernesse, (Huntingdon.)—Almost any maker of chemical apparatus could supply what is necessary. It would not be fair to mention the names of individual firms.

Dr. Swift Walker is thanked.

M. A.'s letter respecting our Public Schools Commission must have his name attached. An anonymous communication would have no weight.

Dr. Bell Taylor.—If possible.

Mr. Robson.—The mistake has been rectified, as our correspondent will find if he will refer back.

American Degree Brokers.

The following letter is sent to us for publication. It was written to one of the assistants of a leading firm of druggists:—

"Packington College, 145, Packington-street,
London, N., Sept. 2nd, 1875.

"My dear Sir,—I can influence you the diploma of A.M. and Ph.D., or B.Sc. or D.Sc., &c., from several Universities in the States; and if you will call here between four and eight or *any time* by appointment, or state a time when you wish me to call on you, I can show you the documents, and give you every information; or if you send the fee (£15), I will send the document at once, with the registration certificate, &c. &c.

"Yours very truly,
"E. Sturman.

"P.S.—You can arrange with me as regards money matters."

Apropos of this subject, we publish from *The Times* the letter of his Excellency the Minister of Education at Washington, in reply to Mr. A. L. Sparkes, of Shelton, Stoke-on-Trent, who had very happily forwarded to that distinguished functionary the letter of that mysterious person in Jersey who considerately caters for those who want degrees *in absentia* at the small cost of £20:—

"Department of the Interior, Bureau of Education,
Washington, United States, August 18, 1875.

"Sir,—Your letter of the 1st inst., enclosing a communication from Dr. ——, dated the 16th of July, 1875, and offering to procure the degrees of Ph.D. and M.A. from the University of Philadelphia for the sum of £20, was received on the 16th inst. In the absence of General Eaton, Commissioner of Education, I sent the documents in question for the examination of Hon. J. P. Wickersham, Superintendent of Public Instruction of the State of Pennsylvania. The Charter of the University of Philadelphia was revoked some two or three years ago on account of the notorious and shameless sale of degrees and similar rascalities. It has no actual or legal existence.

"Allow me to assure you, Sir, that no respectable institution of learning in the United States confers degrees for money. If degrees are conferred at all they are granted with other motives than pecuniary gain. The reason why this particular fraudulent institution has been successful is because the University of Pennsylvania, whose name it imitates, is an institution of great corporate wealth and high intellectual character.

"I return Dr. ——'s letter after taking a copy of it.

"I am, Sir, very respectfully, your obedient servant,
"Charles Warren, Acting Commissioner.

"To A. L. Sparkes, Esq., B.A., Shelton,
Stoke-on-Trent."

A Directory of Qualified Veterinary Surgeons.

To the Editor of The Lancet.

Sir,—May I suggest through your columns to the Editor of the Medical Directory the desirability of appending a carefully prepared list of all properly qualified veterinary practitioners. It is important to country practitioners at least to know what "vets" are legally qualified, as it is presumed that no medical man would knowingly employ an unqualified person.

Yours truly,
Shepton Mallet, Sept. 15th, 1875. F. Porter Smith.

Communications not noticed in the current number will receive attention in our issue of the ensuing week.

Communications, Letters, &c., have been received from—Sir J. Alderson, London; Prof. Gamgee; Sir L. M'Clintock, Portsmouth; Dr. Broadbent, London; Dr. Fothergill, London; Dr. Speedy, Dublin; Mr. Burdick, Chertsey; Dr. Branwell, Brighton; Mr. Sedgwick, London; Dr. Corfield, London; Mr. Kesteven, London; Mr. G. Brown, London; Mr. Robson; Mr. Thoms, London; Dr. Mackintosh, Chesterfield; Mr. H. Ormond, Westbury; Mr. Innes, London; Mr. Walker, Hanley; Mr. Maunder, London; Dr. Mahomed, London; Mr. Reid, Stafford; Mr. J. Martin, Woodford; Mr. J. Robinson, Chester; Dr. Addy, Pendleton; Mr. Morton, London; Mr. Rendall, London; Mr. Davies, Corwen; Dr. Taylor, Nottingham; Mr. Jeaffreson, Newcastle-on-Tyne; Mr. Richardson, Dover; Mr. Stewart, Leith; Mr. Taylor, Hornsey; Dr. Hopkins, Llantrisaint; Mr. Lewis, Burnley; Mr. Brooks, London; Dr. Walker, Aldborough; Dr. Macpherson, Chichester; Dr. Walker, Maidford; Dr. Frodsham, Upper Streatham; Dr. C. White; Dr. Cochrane, Port Patrick; Mr. Giles, Stanton-on-Wye; Mr. Needham, Gloucester; Mr. Prichard, St. Leonard's; Mr. Walker, London; Miss Halker, Lytham; Messrs. Bernard and Co., Leith; Mr. Hall, Thurso; Mr. R. D. Smith, London; Union Surgeon; Z. Y.; Alexis; H. F. P.; E. H.; Delta; M. A.; F. E. P. H.; Chirurgicus, West Bromwich; Hope; &c. &c.

Letters, *each with enclosure,* are also acknowledged from — Mr. Harris, Leighton Buzzard; Mr. Sunderland, Birmingham; Mr. Somerville, Edinburgh; Mr. Carruthers, Coundon; Mr. Stead, Silverdale; Mr. Robinson, Ditchling; Mrs. Miles, Cardiff; Mr. Martin, London; Mr. R. Hordley, Hartshill; Dr. Maclaren, Edinburgh; Mr. Steele, Stoke; Mr. Butler, London; Dr. Hains, Norwich; Mr. Miller, South Brent; Mr. C. E. Ellis, Rotherham; Mr. Davies, Moriston; Mr. Moore, Cheltenham; Mr. Gell, Southam; Mr. Garforth, Sheffield; Mr. Jones, Llanfyllin; Mr. Green, Hoyland; C. R.; M.D., Bishop Auckland; Medicus, Burham; C. H. T.; Chirurgus; C. M., Waterford; M.D., Bath; W. M. S., Tunbridge Wells; Medicus, Leeds; F. W., Bushey; G. N., London; An Enquirer; F. T. B.; F. W.; B. A., Portmadoc; Ferri; J. S., Oldham; M. A., Aberdare; J. B.; E. L. O.; J. M. P.; W.; J. C. F.; R. N. M.

Surrey Advertiser, Birmingham Morning News, Leighton Buzzard Observer, Newcastle Chronicle, Manchester Guardian, Metropolitan, Edinburgh Daily Review, Cork Constitution, Huddersfield Chronicle, Western Morning News, Liverpool Post, East London Observer, Western Daily Press, Record, Merthyr Express, Grimsby Observer, Daily Bristol Times, Saunders's News-Letter, and *Isle of Man Times* have been received.

Medical Diary for the ensuing Week.

Monday, Sept. 27.

Royal London Ophthalmic Hospital, Moorfields.—Operations, 10½ A.M. each day, and at the same hour.
Royal Westminster Ophthalmic Hospital.—Operations, 1½ P.M. each day, and at the same hour.
St. Mark's Hospital.—Operations, 9 A.M. and 2 P.M.
Metropolitan Free Hospital.—Operations, 2 P.M.

Tuesday, Sept. 28.

Guy's Hospital.—Operations, 1½ P.M., and on Friday at the same hour.
Westminster Hospital.—Operations, 2 P.M.
National Orthopædic Hospital.—Operations, 2 P.M.
West London Hospital.—Operations, 3 P.M.

Wednesday, Sept. 29.

Middlesex Hospital.—Operations, 1 P.M.
St. Mary's Hospital.—Operations, 1½ P.M.
St. Bartholomew's Hospital.—Operations, 1½ P.M., and on Saturday at the same hour.
St. Thomas's Hospital.—Operations, 1½ P.M., and on Saturday at the same hour.
King's College Hospital.—Operations, 2 P.M., and on Saturday at 1½ P.M.
Great Northern Hospital.—Operations, 2 P.M.
University College Hospital.—Operations, 2 P.M., and on Saturday at the same hour.
London Hospital.—Operations, 2 P.M.
Samaritan Free Hospital for Women and Children.—Operations, 2½ P.M.

Thursday, Sept. 30.

St. George's Hospital.—Operations, 1 P.M.
Royal Orthopædic Hospital.—Operations, 2 P.M.
Central London Ophthalmic Hospital.—Operations, 2 P.M., and on Friday at the same hour.

Friday, Oct. 1.

St. George's Hospital.—Ophthalmic Operations, 1½ P.M.
Royal South London Ophthalmic Hospital.—Operations, 2 P.M.

Saturday, Oct. 2.

Royal Free Hospital.—Operations, 2 P.M.
Charing-cross Hospital.—Operations, 2 P.M.

NOTICE.

In consequence of The Lancet being frequently detained by the Post Office when posted for places abroad *more than eight days after* publication, subscribers and others are reminded that such copies can be forwarded only as book packets, and *prepaid* as such.

TERMS OF SUBSCRIPTION TO THE LANCET.

Post free to any part of the United Kingdom.

One Year .... £1 12 6 | Six Months £0 16 3

To the Colonies and India.

One Year £1 14 8

Post Office Orders in payment should be addressed to John Croft, The Lancet Office, 423, Strand, London, and made payable to him at the Post Office, Charing-cross.

TERMS FOR ADVERTISING IN THE LANCET.

For 7 lines and under	£0 4 6	For half a page	£2 12 0
For every additional line ...	0 0 6	For a page	5 0 0

The average number of words in each line is eleven.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday; those from the country must be accompanied by a remittance.

N.B.—All letters relating to Subscriptions or Advertisements should be addressed to the Publisher.

Agent for the Advertising Department in France—
Mons. DE LOMINIE, 208, Rue Grenelle St, Germain, Paris.

Introductory Address[1]

DELIVERED AT

ST. GEORGE'S HOSPITAL,

October 1st, 1875.

By ROBERT BARNES, M.D.

It is generally felt that the hardest duty that can be allotted to a teacher is to make him give the "Introductory" on the opening of the medical session. The feeling therefore with which I accept the honour awarded to me is not one of gratitude without alloy. At the same time I cordially acknowledge the graceful and kindly courtesy which prompted my colleagues thus to initiate my return as a teacher to the school in which I am proud to have been a student. I have been a vagabond over London dragging at each remove a lengthening chain, but still, holding on by the instinct of affection, it has brought me home at last.

One of the penalties of my wandering career is that I am now called upon to give my third "Introductory." The difficulty of acquitting oneself becomingly is not, I am afraid, diminished by experience. The choice of a theme becomes more contracted, and the difficulty of illustrating the theme that may be chosen is increased by the conditions under which these addresses are now delivered. Not many years ago the introductory lecture was a purely intra-academical discourse. It was almost invariably confined to historical disquisition, to praise of one's own school, to an exposition of the curriculum of medical study, concluding with a homily to the students on the text of diligence and good behaviour. All of this is somewhat trite; and the homily I venture to say is a work of supererogation. But with the rapid advance of medical knowledge, and its consequent extending influence upon legislation, statutory and administrative, medical education and the preceedings of our medical colleges are now invested with a degree of public interest previously unknown. Altered circumstances, therefore, seem to invite, if not to compel, those who have to give these addresses to select for their theme some of the wider and more general aspects of medicine; to endeavour to point out some of the relations of medicine to the public good; to expose some of the defects in the construction or administration of our laws that hinder the just and beneficent application of science to the public service. Thus, we may suggest to you some idea of the higher aims of the profession you have chosen, of the position you will occupy in relation to other professions and to society at large, and of the duties that devolve upon you in maintaining and extending that influence upon which the future welfare of mankind so largely depends. What was once called the "healing art" has now a far greater sphere than the term expresses. Medicine in its modern sense and work is "preventive" as well as "healing." Medicine is no longer simply an art directed to the alleviation or cure of individual suffering. Applied to the task of aiding in the administration of justice, of removing the causes of disease, of restricting or annihilating epidemics, of increasing the sum of national health, it becomes a moving power in government. State-Medicine then is the offspring and the complement of the "healing art."

An education framed in such a manner as to prepare men for duties so vast and so important must be comprehensive in its range, accurate in its method. Medicine deals especially with the phenomena of life. But since life depends upon or is influenced by external conditions, biology is impossible without a fair knowledge of physics. These two departments of knowledge are the foundation and the glory of medicine. The study of them, directed to a practical application—the health and happiness of man—constitutes an education superior to that pursued by any other profession. It is superior in the range and precision of its knowledge; it is superior as an organon for the training of the intellect; it is not inferior in the formation of the higher moral attributes.

That which distinguishes modern medical education is its accuracy. The application of instruments of precision, as the thermometer, the sphygmograph, the stethoscope, the ophthalmoscope, the laryngoscope, and other contrivances for extending sensual perceptions into the interior of the body, together with microscopical and chemical analysis, enable us to observe, to record, and to compare the phenomena of health and disease to such a degree as to bring medicine nearer and nearer to the rank of an exact science.

Medical education possesses this inestimable advantage: its foundations are laid deep and wide in objective study. It is first circumspective, then introspective. It rests upon observation. And yet it does not exclude the play of the imagination. Without this divine faculty we should have few discoveries; and every page of the history of medicine glows with brilliant discoveries. But still the chaotic materials which imagination forges into laws are the fruit of laborious observation. And these laws are being continually tried by the test of fresh observation. Medical science is being incessantly extended and corrected by the interrogation of nature. And nature rarely refuses an answer to the patient and humble inquirer. It is in this court of appeal, always open, that the strength of medicine lies; the source of her controlling power over the schools of theology and law. I should be loth to utter one word of disrespect towards the sister faculties. Society could not exist without religion and without law. But I hope to be forgiven for pointing out that both religion and law will be strengthened the more they are brought into harmony with science. Each is the complement of the other two. But the day has come when science must lead. The last-born, perhaps, now that the day of her emancipation has arrived, the most vigorous, the most progressive, and therefore destined to exercise the greatest sway in the future. Theology and law are in their essence stagnant. Religion is wholly revealed. Presumption alone can add anything to its sublime and simple truth. Law, when not informed and vivified by science, is dogmatic—the slave of authority seeking a solution of its doubts in precedent, which is too often nothing more than error upon error crystallised by time. And so it must be with an almost purely subjective study. Deriving the bulk of his knowledge from oral or written tradition, the lawyer, according to the bent of his organisation, assimilates what he learns—makes it a part of himself. It thus undergoes a subjective transformation. And since men's minds differ in their constitution and construction, there results an infinite diversity of opinions, whilst there is no appeal but to the opinions of those who have gone before, and who from that very circumstance are more likely to be wrong than themselves. Hence those incessant conflicts in our law-courts, those frequent reversals of the decisions of one civil court by another, which are the despair of the uninitiated. If there were a court of appeal in criminal cases, reversals would probably be no less frequent; and still greater would be the difficulty of the Irishman, who, when asked to plead Guilty or Not guilty, replied, "'Faith, how do I know till I'm tried." Recently the Legislature has decreed certain changes in the machinery and proceedings of the law. I dare not, with profane hand, touch this mystery of mysteries. Let us hope that the changes will result in more speedy justice and diminished bills of costs.

Since the function assumed by the law is not to add to human knowledge, and since laws must in the end be brought into harmony with knowledge, it might be expected that law-makers and law-administrators would accept with more deference than is often shown the teachings of those who have made science the occupation of their lives. The obvious objection urged is, that the teachings of science are themselves conflicting. But it is equally obvious that those who make science their study are more likely to be right on questions of science than those who trust to their common sense. As Whately put it: no one would trust himself to navigate a ship by common sense. The skilled sailor may sometimes founder, but the rash landsman is pretty sure to come to grief. Still, making full allowance for the necessity of caution, admitting that science must always be in advance of law, we may not unreasonably complain that law lags so very far behind; that it limps along with such hesitating step.

There are certain flaws, which are a real discredit to the law, which involve inconsistencies so gross as to be revolting not alone to the scientific mind but to the sense of the community. Of these, let me instance the well-known practice when pregnancy is pleaded in bar of execution. The law directs that the prisoner shall be examined, not alone as to the bare fact of pregnancy—in itself sometimes no easy task for a skilled physician,—but also as to whether she is "quick" with child. This latter fact it is often impossible to determine. In the first place, the so-called "quickening" is with many women an entirely subjective phenomenon—a sensation they think they perceive, but which is not perceptible by others. She may affirm that she is conscious of having quickened, and the examiner is not in a position to refute her assertion because he or she may not obtain objective proof. In the next place, some women never consciously quicken at all, and the examiner may equally fail to get evidence of the event. And many women quicken, or think they do, who are not pregnant. Again, the movement or impulse felt by the examiner, and which is presumed to be proof of a "quick" child, is often fallacious. The late Dr. Tyler Smith insisted that the movements felt by the mother and by the examiner were not produced by the child, but by the womb itself; and it is now known that these movements of the womb can be detected before the earliest period assigned for the quickening of the child.

We ought perhaps logically to begin by defining the condition of being "quick with child." Lawyers, I am afraid, sometimes find a malicious pleasure in pressing scientific witnesses for a definition. No skilled witness would, I venture to say, attempt to define this condition. It is a legal fiction, not a natural fact. The burthen of definition, then, rests with the lawyer. It is absurd for him to appeal to science for an answer. The legal definition is, I believe, as follows: "The term," says Taylor, "is derived from the old Saxon word 'quick,' signifying living; as, at the time when medical science was in its infancy, it was considered that the fœtus only received vitality when the mother experienced the sensation of its motion"! I need not point out the shocking absurdity of this doctrine. I cannot suppose that any lawyer now believes in it. But the law exists; so that we are driven to conclude that those who keep it on the statute-book respect the law more than the truth. But the climax of absurdity is reached when the determination of this abstruse problem, this impossible fact, is left to twelve matrons who may happen to be in Court. As Dr. Leake irreverently observed, the judge who should call upon twelve old women to execute this function must himself be an old woman. But I have known it done twice; and twice did the discreet matrons declare the prisoner "not quick with child"; and twice did skilled examination, and time, the solver of mysteries, prove that the prisoner's plea was good.

After all, then, it may be answered, the appeal was made to science in time, and no harm was done. The law directs the judge to empannel a jury of matrons, but does not preclude him or the Secretary of State from referring the decision to an expert. I do not believe that a pregnant woman, who pleads her pregnancy, will ever again be hanged on the verdict of a jury of matrons, unless, indeed, we are destined to see juries of matrons selected from legally qualified "medical women." This may happen when Macaulay's Lord Chancellor will be sitting on the woolsack with twins in her lap. Let us hope not before.

But the absurdity, the barbarity of the law in this relation does not end here. The law of England makes it felony to attempt to procure abortion. All right-minded persons will admit the wisdom, the justice, the necessity of this provision. But then see how lamentable is the inconsistency of the law. It declares that a pregnant woman may be hanged; it makes it felony to attempt to procure abortion. Justice in this case sanctions, nay, commits homicide and fœticide; and with blind inconsistency punishes those who are guilty of the simple attempt to procure abortion. It is scarcely an extenuation to urge that the shocking consequences that would result if the letter of the law were rigorously carried out are practically avoided. It is no small evil that a law representing ignorance so gross should disfigure the statute-book, and that practice so clumsy and ridiculous should stain the records of our courts. The indirect influence of authorised error cannot fail to be pernicious. When the judges thus sanction the theory that the embryo in its early stage has no life, and may be treated as non-existent, how can it be expected that the ignorant masses will look upon the procuring abortion as a crime? This most deplorable doctrine is not accepted in other countries.

There are other questions connected with this subject which scarcely appear to have been contemplated by the law, and which in the interest of humanity and justice ought to be considered. We have seen that a woman may be pregnant and not know it; thus, not pleading her pregnancy, she may be hanged, and the intention or the spirit of the law is frustrated. Again, a prisoner may be pregnant, and, knowing it, suppress the fact, suffer herself to be hanged without pleading; and thus again is the spirit of the law frustrated.

Here we are brought face to face with another relic of the age of ignorance which is still held in bigoted veneration. The irresponsibility of the insane is a question that is continually giving rise to the most painful discussions and the most conflicting decisions in our courts. In all civilised countries it is a fundamental rule that responsibility is the attribute of reason, and, therefore, that insanity implies irresponsibility. In its dealing with this admitted principle the courts practically abrogate the law. The judges, many years ago, in deliberation, put a definition upon the law, upon which their successors still hold themselves bound to act. This definition virtually declares that insanity does not carry irresponsibility. Their faith in the wisdom of their predecessors is absolute; their contempt for the teaching of modern science is unbounded. On a recent trial the learned judge (Brett) thus charged the jury:—"It was not sufficient to show that the prisoner was insane, unless it was also shown that he did not know the nature of the act he was committing, or did not know that it was wrong. The jury must disabuse their minds of the medical notions as to insanity, for the reason that these medical men had not met the court upon the ground which they desired them to do, and that their opinions were founded on their own ideas as to what the law of insanity ought to be." Notwithstanding this charge, the jury, without any hesitation, found the prisoner not guilty, on the ground of insanity.

The late Lord Campbell once said to a distinguished physician, who was giving evidence in a case of insanity, and who had been obliged to use the term "homicidal insanity": "Homicidal insanity! I will not allow those words to be used in my presence!" But this emphatic judicial repudiation did not alter in the slightest degree the fact of the existence of a type of mental derangement which manifests itself by homicidal propensities, and which psychologists will, until they discover a better name, continue to designate "homicidal insanity." But another Lord Chancellor went beyond this. After the Windham commission, he actually proposed to exclude medical evidence in commissions of lunacy, except in so far as it was based on *facts* within the personal knowledge of the witnesses.

Primâ facie, to establish insanity is to establish irresponsibility. Upon medical science it falls to make good this *primâ facie* case. And, having done this, the universal contention of those who have made lunatics and insanity their study, by clinical observation and other methods of research, is that they have done enough. They know the absurdity of attempting to reconcile reason and unreason, health and disease; they know that insanity, where it exists, alters the whole man; they know that a diseased organ cannot work healthily. Observation tells them that man, complex though he be, cannot be sane and insane—that is, responsible and irresponsible, at the same moment. Cases, indeed, there are, but they are not common, in which monomaniacs, as they are called, may appear sane until their particular delusion is hit; but it is a gross and dangerous, albeit a popular, error, to conclude that these persons are really sound even in part. They are more or less under the dominion of their craze; it underruns the whole current of their thoughts; it may at any moment sway them irresistibly. Surely the creed of phrenology is the foundation of the legal doctrine of coexistent sanity and insanity. If we suppose the mind to be made up of distinct faculties, as perception, comparison, volition, and so forth, each faculty having its own separate organ, it is possible to conceive that one of these faculties may suffer alone when its particular piece of brain is diseased. Lawyers, then, are phrenologists. I do not know whether they will accept this suggestion. It is, however, the best explanation that can be offered of their theory. True science repudiates it. They treat insanity as a purely metaphysical subject. They disregard the dependence of the mind upon the state of the brain. In Carlyle's "Sartor Resartus" is a world of wisdom. If the outward apparel of a man can sway his thoughts and character, how much more then will the condition of the brain and nervous system, upon which perception and reason depend, influence the mind. The metaphysical method of studying the aberrations of the mind is about as reasonable as were the speculations of the ancients upon the circulation of the blood and disorders of the heart before the discovery of Harvey. The basis of all sound knowledge of insanity must be anatomy, physiology, and clinical observation. To neglect this is to flounder in hopeless error.

What the judges declared to be the law, was not really the law, but their arbitrary interpretation of it. We may claim the liberty to question whether this interpretation be the just one. It hangs upon an impossible postulate. No man who has been at one time sane, and therefore trained in accordance with the modes of thought of his fellow-men, can, even on becoming insane, be freed altogether from the influence of that training. The sense that killing is wrong may remain. It is transcendently absurd to look for a man so demented as not to know that striking another man on the head with an adze is likely to injure or kill him. Such a man can hardly be found in a lunatic asylum; and, *à fortiori*, can hardly be found out of one. He is a creation, not of nature, but a legal figment. Carried to its legitimate applications, the legal doctrine would simply abrogate the law of irresponsibility on the ground of insanity. The doctrine, then, must be revised by the light of science; for assuredly juries will continue to reject it. In spite of strong dictatorial charges, it is becoming practically obsolete. It must at no distant date be given up even by the lawyers.

The doctrine that it is right to punish, even to hang, madmen according to their knowledge of right and wrong, ought, in its logical application, to embrace a graduated scale of responsibility and penalties. The attempt to define the degrees in this scale will hardly be undertaken even by the trained analytical subtlety of lawyers. The truth is that only one line of demarcation is possible. That line must be drawn with a resolute hand between sanity and insanity: responsibility on the one side; irresponsibility on the other.

A not uncommon argument in favour of the legal interpretation is that "the theoretical superiority of the medical criterion is far outweighed by the practical value of the judicial test. Its error on the score of excessive stringency is in practice corrected by the action of the juries." The fallacy of this reasoning is transparent. It is simply to assert that it is right to hang a madman if a jury will allow it. An argument of this genus was used—and too successfully—by the Attorney-General (Coleridge) who prosecuted the boy O'Connor for an attempted assault upon the Queen. He represented to the jury that it was better for the boy to be sent to prison for a definite term than to an asylum! To prison he was sent; and there his insanity—the evidence in proof of which had been ridiculed at the trial—became manifest, and he had to go to an asylum after all. The gaol did not cure him. It seldom does cure insanity. In this respect it is inferior to the gallows.

Absolute laws seldom endure long without question or mitigation in practice. Hence we see that whilst judges would, by an arbitrary and untenable definition, abrogate the law that insanity carries irresponsibility, juries with minds untrammeled by traditional authority, open to evidence, accept the opinions of experts on this subject; act upon the spirit of the law; restore it to its integrity; and save civilisation from the revolting spectacle of hanging the insane.

There are two principal provisions by which undue harshness or error in the administration of justice in this country are mitigated or corrected. This corrective action is exercised by the juries, or by the Secretary of State for the Home Department. The Home Secretary's action is usually assisted by the representations of the judge or jury, or by some expression of public opinion. In this way a man who is proved to have been innocent of a crime for which he was convicted is, by a subtle process too perplexing to be fathomed by a plain understanding, "graciously pardoned."

If lawyers meeted out to themselves the same law which is applied to doctors and naval commanders, surely they ought, when a prisoner is wrongfully condemned, to be themselves subject to action for damages or to a criminal prosecution. It cannot be doubted that innocent men have been sent to the hulks or hanged through the incompetence of their counsel.

Is there no such thing as malapraxis in law? The jury is, however, the best and most trustworthy security against arbitrary law. Originally instituted as the most effectual safeguard against political oppression, the jury now exercises a scarcely less valuable function in checking the arbitrary tendency of the law. Through the jury is felt the wholesome influence of public opinion. Through the jury the due authority of science is often asserted. It is true that juries may now and then reflect popular prejudices; but they can rarely be accused of servility.

Inexorable Time, not unkind to me or to you, warns me not to open new matter, or I might be tempted to say something about sanitary legislation. We have now a sanitary Parliament. Unfortunately there are not half-a-dozen doctors in the House to inform and to control the overwhelming majority of dilettante dabblers, or illegitimate practitioners, in this branch of medicine. No very great success therefore has yet marked a policy whose intention is worthy of all praise. The most immediate result will at any rate be appreciated by our profession. The doctors are to do nearly all the work, with little moral help, at no small personal risk, for very little substantial pay. So much money is wanted for law, and for defensive and destructive armaments, that we must economise somewhere. As a humble Conservative I venture to hope that our chief will continue to educate his party to the conviction that a successful sanitary policy can only be carried out by a proper appeal to medical science, and a more liberal treatment of medical practitioners.

I must, however, refer to a matter immediately related to my theme: the mode of taking scientific evidence. I think it will not be denied that, howsoever excellent the practice in force may appear to lawyers, it is eminently unsatisfactory to experts. Seldom, probably, does a scientific witness leave the box quite easy in mind as to whether he has spoken "the truth, the whole truth, and nothing but the truth." And not seldom does he experience the mortification of finding what he said utterly wrested from its proper meaning by the perversity of counsel, or misunderstood by the court and jury. The theory that through the conflict of opposing counsel by examination and cross-examination, and the impartial interrogation of the court and jury, the truth is elicited, often signally fails in practice. The questions of counsel are generally prompted by hints gathered from books, or from experts sitting at their elbows. But they are very wary in accepting these suggestions. They may not understand them; and, if they do, they may in their discretion fear that the answer drawn will damage their case. Thus it constantly happens that the expert is only allowed to say so much of the truth as may suit the purpose of counsel; and everyone knows how detached fragments of truth may be made to support a false argument.

A most serious objection to this interrogatory method is that the knowledge and conclusions of the expert can rarely be given in such a way as to challenge the judgment of his profession. Few experts descending from the witness-box would be content to be judged by his fellows upon his evidence as produced in a court of law. It would be in the highest degree unreasonable to hold them responsible for an exposition of their views, which, if they did not repudiate it altogether, they would desire to qualify materially.

The mode of "getting up" evidence is often a curious illustration of "how not to do it." The choice of experts and the nature of the evidence set before the court is in many cases a pure matter of accident. The initiative set by policemen is often held sufficient. It is left to the discretion of the attorneys on either side to select what witnesses they think proper, the choice on the part of the Crown being commonly restricted by parsimonious instructions, and on that of the accused by poverty. In making a selection, the first consideration usually is to get witnesses whose evidence will fit in with the theory of the prosecution or the defence. Great care is taken to avoid those experts who are apt to speak their convictions unreservedly. These are considered "bad witnesses."

Those who are prepared to admit that the perfection of the practice in our courts is a question open to discussion, may probably see in the practice of foreign courts some points not unworthy of imitation. When an offence against the person is suspected, a judge of instruction appoints one or two experts to make the preliminary investigation; these make a formal report in writing, and this report is a document that has to stand the criticism of their professional brethren. It cannot be suppressed by counsel.

It must often happen that the scientific case as presented to a jury is inaccurate and imperfect, and that further inquiry would clear up all doubt. I am not lawyer enough to know whether the superior criminal courts have the power to do what a coroner or a magistrate sometimes does—that is, to adjourn a trial for the revision of the scientific conclusions; but I do not remember to have heard of such a course being adopted. Such a power of adjourning for further evidence would be the most efficacious check upon the perverse ingenuity of counsel in raising a cloud of doubt by insisting upon some defect or point omitted, and which could often be cleared up by proper reference. But this, the true scientific method, is not that of the law. As the case is presented, so it is dealt with. And here again we sometimes see the jury evade the difficulty by not agreeing to a verdict. A bungling proceeding, rather; for the result is simply a miscarriage of justice.

In France the president of the court may call for fresh scientific evidence, and appoint new experts. Men so chosen are more likely to be free from bias than when they are chosen and paid by one side or the other. The way of taking the opinions of an expert in court is extremely ingenious. He is expected to hear the evidence; but he must not give his opinion upon it, for that would be to usurp the functions of the jury. He must answer upon a "hypothetical case" framed by the counsel upon data more or less accurately representing the facts given in evidence. It is not too much to say that the case so put often bears little resemblance to the true one; and the witness may be harassed by a number of discordant hypotheses. But the clumsiness of the process is best shown by the fact that it constantly breaks down; and judge and counsel are continually lapsing into common sense by putting questions directly bearing upon the case. The general effect of the mode of getting up evidence and of examining experts in courts of justice is to deter many of the best men from appearing as witnesses. This is a most serious injury to the public. It involves a virtual suppression or exclusion of the truth.

But I should exhaust your patience long before I could exhaust the false relations between law and science. The illustrations I have imperfectly drawn will serve the purpose of showing you in some degree the higher public duties which lie before you. As science advances, as education spreads, the legislature and the law will be more and more prepared to welcome your aid and counsel. For this, the diligent prosecution of the scheme of study laid down by the examining boards is the best preparation. No pains have been spared in this school to provide all the appliances and opportunities this scheme demands for its full development. These opportunities you will use to your utmost. And if you want a stimulus to industry beyond the vulgar, but very proper, one of fitting yourselves to succeed in life, and beyond the feeling of duty that animates every honest man, you may find it in the glorious traditions of this hospital, where so many illustrious men have worked, and given the example of work. The light which John Hunter, greatest of biologists; of Thomas Young, second as a natural philosopher only to Newton; of Matthew Baillie, one of those who laid the foundations of modern pathology; of Brodie, for intellectual power second to no surgeon of this century, have shed over the whole profession, and, indeed, over the civilised world, shines with peculiar brightness here at the centre, whence it beamed. We might claim these great men as our scientific ancestors. But such men live for ever. Each has left his soul stamped upon works that will last as long as history shall record the achievements of genius for the delight, the instruction, and the welfare of mankind.

Introductory Lecture

ON

MEDICAL EDUCATION; ITS SPIRIT AND ITS METHOD.

Delivered at King's College, London, Oct. 1st, 1875,

BY JOHN CURNOW, M.D. LOND., M.R.C.P.,

PROFESSOR OF ANATOMY IN AND HON. FELLOW OF KING'S COLLEGE, AND ASSISTANT-PHYSICIAN TO THE HOSPITAL.

MR. PRINCIPAL AND GENTLEMEN,—My colleagues have deputed to me the pleasurable duty of addressing to you those words of encouragement and welcome with which, in accordance with a time-honoured custom, we commence the labours of a new medical year. I could have wished, for your sakes, that this duty had fallen on older shoulders than mine; the more especially when I look back on the addresses, laden with wisdom and information, which I have heard in this theatre from some of the senior members of our staff. But though I shall fail in the inculcation of truths that only mature observation and long experience can teach, I must lay claim to an intense and ardent sympathy with the hopes and fears of every student among my audience, for a vivid reminiscence of my mixed feelings of apprehension, wonder, and expectation, on first taking a seat on those benches, has haunted me ever since I accepted the privilege of welcoming you here in the name of the medical staff of this College. I most cordially and sincerely congratulate the new students on their choice of our profession—a profession whose benefits are now so generally acknowledged, and whose duties are increasing so greatly every day. I can promise to them every assistance and encouragement that is within my power and in the power of every and any member of this staff toward the attainment of such knowledge as is necessary for the practice of their duties with that proficiency which will lighten their after-labours and increase the obligations of a suffering humanity. To the older students such expressions are, I am sure, quite unnecessary, and I shall content myself with the assurance of our continued interest in their work, and the wish that every succeeding anniversary of our opening day may find them as eager, as hopeful, and as determined to add to the amount of fair and honest endeavour, as when they commenced their medical studies. All true work lives for ever; but

"Work without hope draws nectar in a sieve,
And hope without an object cannot live."
